humans over all other life forms. Such logic which is rooted in understanding place and land as objects, can give rise to systemic forms of domination by humans such as ownership and exploitation, violence and oppression, not only over land but also over people, language, and cultures (Calderon, 2014; Seawright, 2014).

The importance of place in education is not new and over the past few decades has taken a number of directions. American teacher-scholar Gardner Seawright (2014) examines three directions in his analysis of place, education and settler colonialism: (1) place education grounded in the local that begins with community and environmental issues important to these contexts (e.g., Sobel, 2004); (2) critical consciousness as a philosophy that encourages re-construction or re-learning to live in more relational and holistic ways in place (e.g., Greenwood, 2013); and (3) Indigenous perspectives in which place is considered as a significant relationship between human and more-than-human worlds (e.g., Barnhardt and Kawagley, 2005; Cajete, 1994; Onwu and Mosimege, 2004). A view of place education informed by Indigenous and ecological perspectives focuses on a more “harmonious relationship” between humans and the natural world compared to perspectives that support colonial systems of domination (Seawright, 2014, p. 561). Following Seawright, American scholar Calderon (2014) examines how settler notions of territory or land not only privilege settler access to land but also eliminate and dis-place Indigenous peoples on those lands, severing their deep connections with land, language and culture developed over thousands of years. Land education therefore requires, as Calderon (2014) argues, engagement in studies of place and land beyond a focus on environmental education.

Similarly, Bowers (2017) critiques critical perspectives on place stating that such views focus on power relationships between humans while neglecting the complex power relationship of humans and the environment. Bowers (2008) argues much of the current environmental/cultural ecosystem degradation comes from human domination. He contends that a critical pedagogy of place education does not address these issues as it perpetuates the very philosophical assumptions that contribute to technological capitalism. This, Bowers (2011) asserts, produces double binds (Bateson, 1972) wherein attempts to address a problem only serve to exacerbate it and thereby (re)create the same dilemma.

Understanding place relationally through Indigenous and ecological perspectives enables a more fluid sense of place/land. Rather than a Cartesian or geographically positioned view of place, a more relational perspective allows for place to flow with other places and with human and more-than-human worlds (Rubel and Nicol, 2020). It is important to clarify that we do not advocate for views that essentialize people to a specific type of education (e.g., academic or non-academic/vocational) designed specifically for that place thereby fixing people to that place. Instead, we support educational perspectives that emphasize historical, cultural and environmental distinctiveness of a particular place. However, we also recognize, following Bowers (2015), that places are also made, commodified, named, claimed, and even stolen.

Returning to the river

The Grand Coulee Dam, built with human needs in mind, rose 116 m above the river’s bed. Consequently, the dam was far too massive to accommodate any type of constructed fish passage and as such, severed fish pathways. Salmon were unable to return from the Pacific Ocean to spawn further upstream in BC waters. Canadian governments, when consulted, approved the dam, citing there were no economic losses for BC—salmon spawning above the dam were not considered part of the economy’s commercial fishery. However, Indigenous peoples living upstream and across the international boundary in Canada found they no longer had, as Sylix Elder Hazel Squakin, states, “access to culture ... [for] when you lose fish, you lose culture” (Columbia Basin Trust, 2020).

In 1964 Canada and the United States signed the Columbia River Treaty agreeing on the co-development, regulation and management of the river (Columbia Basin Trust, 2020). The Treaty required Canada to build three dams along the Columbia River Basin from 1967 to 1973. Currently, the dams bring \$120 million (US) to BC each year in power benefits, helping to: control floods along the river’s communities; provide further dam development projects and generator stations; increase economic opportunities; and create low-cost hydroelectricity for BC industries and communities (Columbia Basin Trust, 2020).

Knowledge-(re)cognizing

Styres (2017) offers Knowledge-(Re)cognizing as a third element in her framework of Indigenous philosophies of land. What diverse knowledges support visioning STEM *with place*? Here we explore knowledge sources and perspectives within geographical, linguistic, and culturally diverse settings. This aspect of the framework includes Indigenous teaching practices formed and informed by relationships with land that is, “contemporary (re)memberings of ancient knowledges and very old pedagogies,” (Styres, 2017, p. 81). Examining and increasing our awareness of these relationships and ourselves-in-relation to land provide new opportunities for collective knowing and enacting. “Place is a way of knowing, experiencing and relating with the world” (Coulthard, 2010, p. 79) and thus embraces a broad view including animals and humans, oceans and waterways, and mountains and trees, and ancestors. We acknowledge there are multiple ways of being in/*with* place and thus multiple ways of knowing.

Armstrong (2017) connects language with land, stating “All my elders say that it is land that holds all knowledge of life and death and is a constant teacher ... that the land constantly speaks. It is constantly communicating. Not to learn its language is to die.” (p. 142). What does it mean to speak the language of place, of land? For many it involves observing, listening to the places, attending to experiences of the places we inhabit. Like Glanfield et al. (2020) who offer the term “land-guaging,” Anishinaabe lawyer John Borrows (2018) writes that Anishinaabeg speakers refer to a “langscape” in which language and land form a place “where physical space interacts with human observation to give meaning to the natural and human worlds” (Borrows, 2018, p. 51). Language and meaning therefore are grounded in, or further still, inherently borne of the land. Indigenous languages reflect

this birth, this living, in the language itself. Learning to speak a dialect of Anishinaabemowin, Potawatomi plant ecologist [Kimmerer \(2013, 2017\)](#), writes how the land (the world) in her language is understood as constantly in motion with agency. Similar to other Indigenous languages ([Cruikshank, 2005](#)), and unlike the noun-based English language, Anishinaabemowin is mostly verb-based. It is a language of animacy. [Kimmerer \(2017\)](#) explains:

Rocks are animate, as are mountains and water and fire and places. Beings that are imbued with spirit, our sacred medicines, our songs, drums and even stories, are all animate. The list of inanimate seems to be smaller, filled with objects that are made by people. Of an inanimate being, like a table, we say "What is it?" And we answer Dopwen yewe. Table it is. But of apple we must say, "Who is that being?" And reply Mshimin yawe. Apple that being is. (p. 132).

The English language, on the other hand, refers only to humans and perhaps pets, as being other than "its." Nonhumans are considered distinct and often singular things and objects, even in their absence, as no-thing. Thinking and writing in an inanimate language, emphasizes human thought and knowledge as separate from, and in many cases, superior to the more-than-human world. As such, opportunities to deepen relationships with and acknowledge respect for connections to other forms of intelligence, other ways of being with the world are limited. Things with and in animate languages elucidates human and nonhuman entanglements, and discloses a world alive with agency.

For example, understanding rivers, beavers, trees, and salmon as endowed with agency and wisdom creates a very different kind of coexistence with them—one of respect and humility, one of openness to listen to others. "Imagine," writes [Kimmerer \(2013\)](#) "the access we would have to different perspectives, the things we might see through other eyes, the wisdom that surrounds us" (p. 133). [Kimmerer](#), noting how language limits our ability to show respect for the more-than-human beings of the world suggests that a change in grammar could help us (re)cognize our interconnectedness to all beings. Similarly, anthropologist [Cruikshank \(2005\)](#), in her conversations with Athapaskan and Tlingit Elders (northern Alaska, USA), points to how dominant languages such as English make it more challenging to consider landscapes, mountains, rivers and glaciers as animate and having agency. Language defines our relationships and how we (re)cognize our relationships with others. By (re)cognizing humans as superior beings we diminish and obscure our responsibility to care for the more-than-human world.

Distinguishing the world as animate and inanimate posits one (animate) as more powerful and deserving than the other (inanimate). Métis scholar Elmer Ghostkeeper, says "[f]rom my perspective, I am the land, I am the environment. There is no separation between us and the land. We are 70% air, water and heat—the same as the land" (Ghostkeeper as quoted in [Surkan, 2018](#), para. 5). Scientist and environmental activist David Suzuki expands on this point arguing that viewing our bodies as separate from our world leads to thinking that humans are above and more deserving of the earth's resources (Suzuki in [Films for Action, 2010](#)). Suzuki contends there is no divide between us and the more-than-human world. There is no environment out there, outside of our bodies, that we watch and interact with, "we are the environment ... whatever we do to our surroundings we do to ourselves ... we can't draw a line and say air ends here and I begin there. There is no line. It's in us. It's stuck to us. We are air" (Suzuki as quoted in [Films for Action, 2010](#)). The animate/inanimate dichotomy does not exist.

Forest ecologist Suzanne Simard challenges such a dichotomy as she documents how trees communicate with each other ([Bingham and Simard, 2012; Simard, 1990](#)). Using radioactive isotopes of carbon, Simard found that Douglas fir and paper birch trees communicated using an underground network of fungi, known as mycelium. All trees, Simard contends, form communicative relationships through mycelium, facilitating nutrient, carbon and water exchange. Communication extends beyond resource transfers and to kin recognition—what Simard refers to as defense signaling. Trees respond when a neighboring tree needs support. For example, when Douglas fir were shaded the birch transferred its excess carbon to the fir, and when the birch lost its leaves in the fall while the Douglas fir still photosynthesizing, transferred its excess carbon to the birch. The mycelium threads itself underground. By ensuring these transfers occur, the mycelium sustains itself codependently with trees. Furthermore, Simard and her research team found that older trees with larger root systems have associated larger mycelium networks and therefore more connections to other trees in the network. The research team even found that these older trees recognize their own seedlings, their kin. Named by Simard's team as "mother trees," these old trees when injured also communicated or signaled this through carbon release into the network preparing other trees for a possible new role in the ecosystem.

These examples of STEM with place provide insight into Styres' notion of (re)cognizing human and more-than-human intelligences. The trees, fish, rivers, are considered as kin, part of a neighborhood, a community of living in co-dependency, a family communicating with each other. Conceptualizing STEM in these ways requires awareness of how language and culture frame what is possible and impossible regarding our relationship with one another. How can we (re)cognize the unique intelligence of the more-than-human world and, as [Abram \(2011\)](#) writes, "hear those many voices that do not speak in words"? (p. 16). [Abram \(2011\)](#) makes a strong argument for reconnecting with oral culture, what [Styres \(2017\)](#) might call the act of (re)cognizing very old pedagogies. [Abram \(2011\)](#) writes:

to live in a storied world is to know that intelligence is not an exclusively human faculty located somewhere inside our skulls, but is rather a power of the animate earth itself, in which we humans, along with the hawks and the thrumming frogs, all participate. It is further to know that each land, each watershed, each community of plants and animals and soils, has its particular style of intelligence, its unique mind or imagination evident in the particular patterns that play out there, in the living stories that unfold in that valley, and that are told and retold by the people of that place" (p. 12–13).

These examples of STEM *with place* also challenge frameworks that privilege human-centeredness, and confront what environmental philosopher Plumwood (2014) refers to as the “hyperseparation” of human and nonhumans that “is expressed in denying both the mind-like aspects of nature and the nature-like aspects of the human” (p. 444). As Kimmerer (2013), addresses, even our language separates humans from more-than-human, and in so doing reinforces a false sense of human superiority, agency, and autonomy which in turn blinds us from understanding how interconnected and inter-dependent we are with nature’s ecosystems, Simard’s research questions whether mind is solely a human phenomenon while Ghostkeeper’s “I am the environment” and Suzuki’s “we are air” philosophies deny separation between humans and world. Visioning STEM *with place*, could lead us to be, as theoretical physicist and biologist Stuart Kauffman says “of the earth rather than above the earth” (Kauffman as quoted in Price, 2020). More-than-human worlds are active and intelligent.

Returning to the river

The Columbia Basin dams change every aspect of the river: its speed, depth, temperature, volume, water quality, and what it carries as well as the life it sustains. Flooding mountain valleys displaced thousands of people, flooded communities, submerged Indigenous cultural and burial sites, devastated fish and wildlife populations, and wiped-out access to fertile soil for animal and plant life. Once one of the highest salmon producing rivers in the world, reports now count 106 runs of the river’s salmon as extinct (Northwest Power and Conservation Council, 2020b). However, dams are not the sole cause of salmon depletion or what environmental historian Joseph Taylor (1999) calls the “salmon crisis” (p. 3). The Columbia River receives toxic waste from thousands of pipes along the many tributaries. Factories, industries, wastewater treatment plants, as well as a nuclear reservation, all pump massive toxic chemicals into the river. But such pollution is not new and, in fact, treating the river as a waste deposit goes back as far as the late 1800s (Taylor, 1999).

This story of the Columbia River, of conflict between settler industry and salmon runs, depicts a change in the relationship between humans and fish. What Blackfoot scholar LeRoy Little Bear (2000) refers to as “jagged worlds colliding.” The Columbia River and tributaries flow without conforming to international boundaries. The US–Canada border on the 49th parallel slices hundreds of waterways, but for thousands of years no such border existed. Salmon made their way through cascading rock waterfalls such as those at Kettle Falls, a gathering place for Indigenous Salish groups to trade, harvest, and engage in cultural exchange.

Action-(re)generating

The fourth aspect of Styres (2017) circular framework is Action, a process of (re)generating and working toward actualizing the Vision; in our case, imagining STEM *with place*. For Styres (2017) “action and (re)generation represent resistance to and (de)centering of colonially systemic relations of power and a (re)centering of Indigenous thought” (p. 123). Here an “outcome of action leads to (re)generated and (re)actualized vision through a process that is dynamic, circular, and iterative” (Styres, 2017, p. 123). This meaning should not be taken as synonymous with the Latin meaning of regeneration as “being born again.” Styres problematizes the thinking which such language engenders by describing industrialized forest reforestation practices primarily intended to replenish trees cut down by commercial logging of entire forests.

Here, as with the Columbia River, perpetuating land exploitation and commodification of trees suggests regeneration through reforestation and “could be seen as another form of slavery” (Styres, 2017, p. 124); that is, ultimately, culturally and environmentally destructive practices remain directed toward promoting human material wealth and consumer needs. In considering these choices as ethical rather than preferential choices, Suzuki urges us to think carefully about our relations with land asking: “is the river the veins and capillaries of the land or an opportunity for irrigation and energy? Is the forest a sacred grove or just an opportunity for lumber and pulp?” (Zuckerbrot and Zuckerbrot, 2016). Like Suzuki’s description of a river, Indigenous meanings of (re)generating imbue self-in-relation to land as being “born of the land” (Styres, 2017, p. 124). Such meanings land-guage circularity and connections to the more-than-human world as sentient, (re)membering humans as earth through deep and spiritual relationships *with place* (Styres, 2017). Our paper contributes to conversations about how we, as humans, can bring forth a more-than-human world. STEM *with place* draws attention to imagining goals and purposes for STEM education beyond economic ones whereby pedagogies as more-than-human engender understanding places as teacher.

Returning to the river

We continue to follow the Columbia River from high in the Canadian Rocky Mountain headwaters, across the terrain, through forests, down to the watershed and now out to the ocean. Throughout this paper, the river introduced us to more-than-human ancestors, including forests, rivers, mountains, mosses, fish, and even air. These ancestors, as teachers, invite us to imagine STEM as an ecology, offering lessons and stories of coexistence or what Kauffman calls, “a well-lived life” (Kauffman as quoted in Price, 2020). However, how do we open ourselves to receive these kinds of teachings when the many voices, languages, and ways of communicating “do not speak in words” (Abram, 2011, p. 16)?

(Re)awakening ourselves to the power of our ancestors’ stories requires “synergistic interaction” between storyteller (e.g., forests and their underground fungal networks) and listener (e.g., humans) (Archibald, 2008, p. 33). This involves a kind of listening that requires all our senses to be aware of and attune to the living forms and rhythms of our more-than-human ancestors. Such listening makes it possible to recognize not only the intelligences of our ancestors but also the varied patterns generated and (re)generated by

them. Returning to the river, we realize there are more and different stories if we are reading to listen. Following the river to the ocean waters, we gaze beneath the surface and to the coral reefs. Awake, we turn to these more-than-human ancestors, to further explore STEM *with* place and importantly, to (re)actualize STEM *as* place.

Concluding words: (re)actualizing STEM *as* place through more-than-human ancestor stories

Here as the result of a recursively circular process of (re)cognizing, (re)membering, and learning from corals as one of our more-than-human ancestors, we (re)generate and (re)actualize our Vision of seeing and understanding STEM not only *with* place but *as* place. We wonder what stories the corals, as one more-than-human ancestor, might share with us so that we may (re)generate STEM as land-gauge which (re)cognizes and (re)members humans as Earth? Said another way, and described earlier by [Borrows \(2018\)](#), how might language and land form a place “where physical space interacts with human observation to give meaning to the natural and human worlds[?]” (p. 51). Here we open ourselves to learn from the stories of coral reefs toward imagining STEM *as* place. In turn, we offer four teachings we see as vital to (re)actualizing STEM through renewing relationships with place.

Teaching 1: courage to respect lessons of more-than-human ancestors

Whether arctic or tropical seas, corals have been on Earth, according to scientists, for as long as 400 million years. Today’s coral reefs, which span five to ten thousand years old, embody and recursively carry forth 25 million years’ worth of evolution. Corals are ancestors. Their reefs are the largest biological structures on Earth. Next to humans, corals are the only organisms capable of transforming the planet’s landscape to such an extent. Not only are corals ancestors, from an engineering and technological perspective, they are both the architects and the architectures—i.e., architect(ure)s. Action as (re)generation reveals corals not as things but inherently “[n]ature as a dynamic [life]force” ([Styres, 2017](#), p. 129). Doing so (re)members, (re)cognizes, and (re)centers corals as creators of Earth’s massive land structures as well as the shapers and protectors of the shorelines of continents. For thousands and millions of years, borne of the land, corals are land. Similar to other natural fractal forms such as clouds, mountains, trees, and our circulatory system ([Mandelbrot, 1982](#)), corals deny spatial and temporal linearities ([Purkis and Riegl, 2006](#)). Irreducible, they cannot be simplified. The closer or farther away you look, the more detail you see. The Great Barrier Reef, whether viewed from outer space at 2500 km or at a closer range of 250 m, 25 cm, 2.5 mm, or even through an electron microscope at 25 μ m, demonstrate self-similarity and increasing complexity ([Muir, 2015](#)). As such, scientists ask “whether the fractal patterns observed in the small-scale structure of corals (e.g., [Bradbury and Reichelt, 1983](#); [Basillais, 1997](#)) are related to the scale-invariance observed at reef-scale?” ([Purkis and Riegl, 2006](#), p. 1760).

Teaching 2: being humble to more-than-human intelligences brings humans back down to earth

Now consider *Hexacorallia* (see [Fig. 2](#)) by artist, philosopher, physician, and scientist who coined the term “oecologie” (ecology) Ernst [Haeckel \(1904\)](#). Stunningly detailed, Haeckel’s print provides a glimpse into magnificence of corals as still objects. Yet, corals as dynamically emergent, reveal Nature’s ancient and living architect(ure)s as capable of even greater mathematical, engineering, technological, and scientific eloquence.

Contemporary science writer and artist Margaret [Wertheim \(2017\)](#) explains: “Many species of corals, then [400 million years ago] and now, also have hyperbolic structures, which we immediately recognize by the frills and crenulations of their forms” where “[a] head of coral is actually a colonial organism made up of thousands of individual polyps growing together; collectively organize [themselves] into a mathematical surface disallowed by Euclid’s axiom about parallel lines” (para. 3). We see corals resisting and de-centering human colonial intentions that attempt to fix, limit, simplify, and ultimately abstract. Here Indigenous thought calls heed to corals—“that it is land that holds all knowledge of life and death and is a constant teacher ... that land constantly speaks” and that “[l]and is constantly communicating” ([Armstrong, 2017](#), p. 142). Emergent is an ecological interweaving of intelligence, not solely as a human quality but of Nature as a whole in which the more-than-human world ([Abram, 1996](#)) enacts intelligently “in ways that are often beyond what humans can understand or replicate.” ([Bowers, 2011](#), p. 315) Corals elucidate what “dominant Western epistemology fails to understand ... the natural environment is not reducible to matter and blind forces” ([Bowers, 2011](#), p. 315).

Intelligently so, for hundreds of millions of years, corals exceeded human mathematics. Here, “[h]yperbolic geometry was only discovered in the 19th century, revolutionizing the field of mathematics and eventually paving the way for Einstein’s general theory of relativity.” (Margaret Wertheim as quoted in [Barnett, 2017](#), para 1.) Yet in being coral, corals are wondrously beautiful and eloquent geometer(ie)s. They live “alternative[s] to the Euclidean geometry that we learn about in school, and a form that, over hundreds of years, many great mathematical minds tried to prove impossible.” ([Wertheim, 2017](#), para. 1). Impossible only because the geometry as “measurement of earth or land” ([Online Etymology Dictionary, 2001–2020](#)) was humanly unimaginable. As 19th century mathematician Wolfgang Bolyai tried to convince his son János Bolyai of the futility regarding hyperbolic geometry and to abandon the work, he pleaded—“For God’s sake, please give it up. Fear it no less than the sensual passion, because it, too, may take up all your time and deprive you of your health, peace of mind and happiness in life” (Bolyai as quoted in [Henderson and Taimina,](#)

Fig. 2 Hexacoralla print by Ernst Haeckel. Source: <https://www.sciencesource.com/archive/Ernst-Haeckel-Hexacorallia-Corals-SS21690898.html>.

2001, p. 17). It was also not until 1997 when mathematician Daina Taimina explored through knitting and then discovered through crocheting that tangible models of hyperbolic planes could be made (see [Henderson and Taimina, 2001](#)). The story of mathematician Benoit Mandelbrot's discovery of fractal geometry, like hyperbolic geometry, plays out in a strikingly similar manner (see [Lesmoir-Gordon, 1994, 2016](#)). Humbled by the intelligence of corals, they bring humans back down to earth and connect humans with land.

Teaching 3: honoring the truth of interdependence among humans and more-than-humans

Consider humans with corals again. Humans have evolved to be one species and corals persist as 6000 species ([National Geographic Society, 2019](#)). Averaging not much more than 1.5 cm in diameter and no brain but a simple nerve net extending from mouth to tentacles, corals build among the most diverse ecosystems on the planet. Coral "colonies" "occupy" a mere 0.2% of the total ocean area yet the habitat enabled by these architect(ure)s supports at least one-quarter of all marine animals. These include more than 4000 species of fish, sponges, anemones, sponges, sea stars, clams, crabs as well as other mollusks and crustaceans ([United States Environmental Protection Agency, 2018](#)). The Great Barrier Reef is an ecosystem of more than 350 species of stony corals and millions of marine creatures including 1500 species of fish, 5000 species of mollusks, 215 species of birds, as well as crocodiles, varieties of dolphins, green turtles, whales, and dugongs ([Zimmerman, 2012](#)). Indeed, it is hard to imagine how this is

possible. Next, we describe three land-guage acts of (re)generating wherein we identify insights as they arise while learning about interrelationships among corals and the different animals that make up ocean “colonies.” We consider these land-guaging acts as a way that (re)generatively (re)stor(i)es interdependence as collaborative and mutually beneficial; lived and living; and, dwelling and (re)building.

First, within coral colonies, algae that inhabit the stony coral polyps photosynthesize and produce almost all nourishment which the coral polyps need to live. The corals in return make proteins, fats, carbohydrates, calcium carbonate, secreting an exoskeleton which provide shelter, minerals, and carbon dioxide which the algae must have to survive. These actions contrast starkly with human colonial practices of dominance that separate the natural world including humans, as “lesser” and “other” to gain cooperation from them with the sole purpose of controlling and exploiting them. Cooperation between algae and coral is not only mutually beneficial but absolutely essential to the survival and flourishing of both creatures.

Second, while alive, stony corals continuously secrete calcium carbonate which extends the reef’s foundation by enlarging their individual skeletons and adding chambers underneath. Even when the polyps die, their skeletons remain and become the foundation for new coral polyps—billions—to attach and continue the building process of the reef through further layering on from the previous skeletons. In this way, (re)generating of the reef necessitates both those corals which are living and those which have lived.

Third, creatures other than corals and algae also play integral roles in creating the complex architectures of reefs. Red algae, for example, produce their own encrusting structures that preserve and keep fragments or loose sediment attached to the reef which would otherwise wash away. And, marine animals such as clams, snails, and sponges that live out their lives in the crevices and holes of reefs eventually die and become the land on which new coral polyps grow. Through the reciprocal process of life and death, remains left behind by these dwellers continuously and regeneratively rebuild the reef.

Teaching 4: wisdom of land for sustainability

Following the Columbia River out to the ocean and turning our gaze beneath the water’s surface teaches us much. What we learn from corals is that (re)generative action both ecological and consistent with Indigenous thinking is inherently “dynamic, circular, and iterative” (Styres, 2017, p. 123). That the survival of the reefs is not simply and singularly driven by one species of coral or even the six thousand species of them. Rather, survival, strength, and innovation necessitate imagining sustainability as something very different than “conserving an ecological balance by avoiding depletion of natural resources” (Sustainability, 2020). Sustainability here implies living life forth as complex, sacred, and regenerative interdependence. In keeping with Styres’ framework (2017), sustaining coral reefs *as place*, *as land*, *as Earth*, does not imply regeneration as “being born again” or merely preventing the depletion of natural resources—e.g., engineering temperature tolerant corals. Instead, magnificently as life and death, corals and their co-inhabitants are always selves-in-relation to Land, born of the land, *as Land* (Coulthard, 2010; Ghostkeeper in Surkan, 2018; Styres, 2017). Corals enable us to understand how (re)generation can serve to further STEM, now imagined *as place*. Here arises land-guage that circles back and (re)members STEM *as place*, deeply and spiritually connected “to ancestors, lands, waterways, and mountains” (Styres, 2017, p. 124).

We see opportunities for (re)centering place/land education with STEM for (re)membering very old pedagogies of the river, forests, and coral that teach us to (re)cognize intelligences in a more-than-human world, and (re)generate STEM *with* place and *as place*. STEM *with* place emphasizes our interdependent relations and the role of place as teacher and mentor. STEM *as place* inspires collaboration beyond human worlds, moving us toward being with the world in new ways, a kind of mutual flourishing and recognition of interdependence. Ramámuri scholar Enrique Salmón introduces the concept of kincentricity to express this relationship in which humans are directly related to all of the natural world including animals, plants, and even stones (Salmón, 2017). A Ramámuri worldview, writes Salmón (2017):

[d]oes not differentiate or separate ontological spaces beyond and between the human and nonhuman worlds. We feel that we are directly related to everything around us. The trees are us; we are the trees. I am rain; rain is me. The rain is all around me; it aligns inside me. (p. 25)

Kincentricity describes STEM *with* place and *as place*. It centers kinship and with it a responsibility to honor and recognize not only the rights of humans but also more-than-humans in interdependent relations. Kincentricity acknowledges the rights of codependent systems to be generative and sustaining including the rights of rivers to flow, of coral to be architects, and forests to share wisdom. Kincentricity situates humans and STEM in relation within a more-than-human world, one where well-being reaches beyond simply a single person, peoples, or species. In doing so, we appreciate the challenge that moving beyond human contexts poses, especially now where silencing and privileging certain groups over others diminishes opportunity for all humans to live well. At the same time, understanding STEM *as place* prompts dialog and caring for the world’s current challenges: species degradation, climate change, sea levels rising, human population increasing, and new pandemic viruses like COVID-19.

“Land is a living entity, and it is constantly in conversation with those of us who know how to listen to it” (Salmón in conversation with Young, 2021). Rivers, forests, corals, and other more-than-human relations and ancestors continuously teach by enacting courage, humility, wisdom, truth, life and death on Earth. Hearing their stories, both ancient and current, brings awareness that humans are in an ethical space with more-than-human relations. This awareness opens us to not only imagine STEM *with* place, but also bring hope that humans might listen deeply and radically live STEM *as place*.

Socioscientific issues in the context of STEM education

Socioscientific issues (SSI) are debatable and ill-defined problems that have a basis in science but necessarily include moral and ethical choices and cannot be resolved through science alone (Ratcliffe and Grace, 2003). As such SSI can provide meaningful contexts for students to learn concepts and practices in science, technology, engineering, and mathematics (STEM) disciplines (Zeidler et al., 2005). As an educational reform, SSI parallels other reform efforts, such as teaching through science inquiry, the engineering design processes, technological literacy, mathematics and computational thinking, and environmental education, while remaining distinct in focus and application. This article explores SSI in the landscape of parallel educational reform movements, the goals of STEM education, and how SSI can provide an avenue for attaining what are often viewed as disparate goals. The article concludes by highlighting challenges to SSI implementation found in the literature. These challenges are followed by potential avenues to foster and support SSI implementation in STEM through teacher education and professional development.

Similar to science inquiry that promotes development and testing of scientific models through evidence-based argumentation (Abd-El-Khalick et al., 2004), SSI allows students to identify arguments and counter arguments based on models (Albe and Gombert, 2012). As science inquiry promotes understanding of and experience with the nature of science, that scientific knowledge of the natural world is tentative and relies on iterative science inquiry processes of evidence-based explanation and argumentation from people of all cultures (Flick and Lederman, 2006). SSI contexts also provide ways for students to enhance science content knowledge, the ability to study the empirical and culturally embedded nature of science, and ability to evaluate different assumptions and claims made during the discussion of SSI (Akerson et al., 2009). However, unlike science inquiry that focuses on the systematic and iterative process to understand the natural world (National Research Council, 2012), SSI cases can go beyond the study of nature extending to areas such as citizenship education (Barrue and Albe, 2013) and character and values (Lee et al., 2013).

The engineering design process and SSI also share common features. Both allow for the exploration and development of knowledge, skills, and technologies to solve problems, taking into account multiple factors such as safety risks, cost analyses, alternative routes, etc. (Guzey et al., 2016). According to the Standards for Technological Literacy, students need to develop understanding of the attributes of design, the engineering design process, and the role of research and development as well as experimentation in problem solving (International Technology Education Association, 2007). The engineering design process includes defining the problem, imagining possible solutions, planning investigations, and creating, testing and redesigning prototypes (Cunningham, 2018). In addition to the engineering design process, technological literacy engages students to develop an understanding of: (a) the cultural, social, economic, and political effects of technology, (b) the effects of technology on history, society and the environment, and (c) the designed world such as medical and biotechnologies, energy and power technologies, and information technologies (ITEA, 2007). Depending on the SSI and how it is incorporated, there can be significant overlap between SSI and engineering design. For instance, learners may compare and contrast alternative energy sources (solar, wind and water) in terms of efficiency and cost, use the engineering design process to create and test model windmills, and examine the impact of cultural practices on energy consumption and carbon footprint (Macalalag et al., 2017). However, while engineering design revolves around systematic and iterative problem solving, it does not always consider the political, moral, ethical, and cultural aspects of the problem, components central to SSI (Zeidler, 2016).

Mathematics and computational thinking play an important role in STEM education. In science, mathematics and computation allow students to collect, analyze and represent data from their investigations, investigate and interpret models from computer simulations, and study patterns and predict behavior of physical phenomena or systems. While in engineering, computer simulations allow students to test, collect data, retest, and redesign their prototypes. Mathematics can also communicate aspects of design features and characteristics (National Research Council, 2012) through real-world connections for mathematics concepts. For

instance, mathematical modeling is a process of interpreting, testing, and revising general real life situations or complex systems (Kertil and Gurel, 2016). According to Gainsburg (2008), real-world connections in teaching mathematics can potentially enhance students' understanding of mathematical concepts, motivate learning of mathematics, and apply concepts to solve real world problems. However, according to her study, most real world connections were brief and many were made by teachers and not by students. SSI can offer a means of addressing this concern by providing an engaging context for applying mathematical concepts to real world scenarios that are culturally relevant to the student. The moral and ethical decision making embedded in SSI requires students, not just the teacher, to connect content to the real world scenarios.

The study of environmental education has been influential in STEM education in recent decades, providing beneficial education on the outdoors, land and wildlife conservation, urban studies, and sustainability, to educate society on how to improve the quality of the environment (Tilbury, 1995) and educate the community about the interdependence of sustainable development and conservation (Gough, 2014). With this focus on modifying our behavior to encourage the use of less damaging alternatives to the environment, environmental education has brought forth the need to bridge the gap between economic development and environmental conservation, and develop a greater understanding of environmental concerns in socioeconomic and political contexts (Tilbury, 1995). Like environmental education, SSI has provided new ways for students to learn about renewable energy sources (e.g., nuclear power) and methods to reduce carbon emission and its effects on the climate (Lee et al., 2012). SSI has also influenced the examination of cultures, politics, and economic factors in the consumption of sea resources and water pollution (Tal and Kedmi, 2006). However, SSI provides focus on the moral and ethical aspects situated within the underlying social and political contexts of environmental issues (Macalalag et al., 2019) such as examining the proponents and consequences of fluoridation of public water supplies, fast food health risks, and stem cell research (Eastwood et al., 2012).

The goals of SSI in STEM education

SSI is firmly situated in the landscape of educational reform and has been shown to have the potential to address the concerns and sometimes apparently disparate goals of STEM education. According to the landmark report *Science for all Americans* (Rutherford and Ahlgren, 1991), STEM courses should "equip [students] ... to participate thoughtfully with fellow citizens" (p. xiii). Presently the *Framework for K-12 science education* (NRC, 2012) holds a prominent place of influence for science teachers while also fostering connections to engineering and environmental topics. That document conveys that learning outcomes from STEM courses should improve the "civic decision making [that] is critical to good decisions about the nation's future" (p. x). It goes on to say that students need to learn about science and technology so they can "engage with the major public policy issues of today" (NRC, 2012, p. 7). However, while there is a clear consensus that STEM education must contribute to the students' ability to deal with scientific issues as they appear in their lives, there is no similar level of agreement as to what kind of classroom experience is best suited to that outcome. SSI researchers have argued that presenting technical knowledge as isolated and divorced from the context of its use is insufficient, given that the goal is to educate people to be able to solve problems that are not entirely technical (e.g., Levine Rose and Calabrese Barton, 2012; Ryder, 2001; Zeidler, 2016).

Feinstein (2011) claimed that the aim should be to prepare "competent outsiders", whom he describes as those who see that "scientific knowledge and knowledge about science are both relevant and accessible—that someone starting on the outside of a problem, without much background, can plunge into the deep water of conflicting expertise and emerge with something resembling an answer" (p. 182). If STEM schooling is geared toward this, it can attend to a longstanding, recognized need for students to recognize what they learn about in school as a relevant and necessary part of navigating their own life and sustaining their cultures (Ladson-Billings, 2014). SSI meets this need by centering on moral and ethical issues, thus rendering the STEM disciplines as an important and relevant contributory means of addressing these issues (Feinstein et al. 2013; Hodson, 2011; Ratcliffe and Grace, 2003). Through addressing moral and ethical issues founded in science-based content, but often left out of traditional STEM education, SSI can offer an authentic immersion into why science matters to all kinds of people in their lives beyond school (Layton et al., 1993). For teachers, this means organizing their curriculum and instruction in ways in which the clarification and resolution of SSI themselves can be the driver of student learning (Sadler, 2009).

A primary reason to pursue SSI is that it can make STEM thoroughly relevant, provided teachers can be responsive and inclusive of their students' interests in and connections to STEM (Basu and Barton, 2007). The potential for SSI to achieve relevance through context is also indicative of its key challenges. As the term "socioscientific" implies, it provides an avenue to marry "the social" with "the science", yet many teachers may not see this as a virtue. STEM teachers tend to identify as authoritative explainers of their discipline's knowledge and instruct accordingly (Levinson, 2004). When teachers do pursue SSI, they are often ill-prepared to implement appropriate forms of instruction (Owens et al., 2019). The main goal of SSI teaching is to achieve what Ryder terms functional scientific literacy (2001), a construct of literacy that is active and seeks to bring the discourse that the public actually engages with science into the classroom. Discourse involves the ways of speaking, thinking, and acting that separate and identify a specific group or network (Gee, 1988) and the scientific discourse in functional scientific literacy must involve the tools needed to thoughtfully negotiate SSI (Sadler et al., 2006). Teachers implementing SSI to foster functional scientific literacy necessarily must model the desired discourse practices (Johnson et al., 2020b). Thus key questions remain that will determine if SSI reforms are successfully implemented: Do teachers have the motivation and disposition to incorporate the extra-scientific components within a STEM content course? Are teachers clear about the pedagogical and content knowledge required for SSI implementation, even as they seem to agree with its basic premise? Will they find their school context to be supportive of enacting SSI? The remainder of this article will

highlight the challenges to reform found in the literature on SSI. Following these descriptions, we will present potential avenues to foster and support SSI implementation in STEM through teacher education and professional development.

Teachers' sense of purpose in teaching STEM

The success of any classroom reform effort is largely dependent on the commitments of the teacher meant to enact it (Haney et al., 1996). Sadler et al. (2006) explored whether and how teachers incorporated ethics, a core element of SSI, into their science teaching. Their findings indicated that many did not because they felt that science classrooms should be value-free. Levinson (2004), in a large survey of British teachers across scientific and non-scientific disciplines, came to essentially the same conclusion. These findings speak to the typical sense of purpose that STEM teachers have regarding their work: successful preparation in STEM evidenced by students' greater acquisition of content knowledge. However from an SSI perspective, this notion of a value-free STEM classroom that does not intentionally make connections to students' cultures is problematic for two reasons.

First, representing the STEM disciplines either implicitly or explicitly as acultural and value-free is a misrepresentation of those fields. Science teachers and science education reformers often hold a misconceived notion of scientific objectivity as a product of its removal and protection from the influences of culture and values (Johnson, 2011). Aikenhead (1996) stated that, "Science curriculum, more often than not, provides students with a stereotype image of science: socially sterile, authoritarian, non-humanistic, positivistic, and absolute truth ... To suggest that school science can present science as culture-free is simply to characterize the subculture of science by its stereotype features" (p. 10). This version of science does a disservice to students who need to engage with science in life by leaving them unprepared to deal with complex issues that involve both scientific and non-scientific epistemologies (Aikenhead, 1985). Chinn and Malhotra (2002) wrote, "When students learn an oversimplified, algorithmic form of scientific reasoning in school, they are likely to reject scientific reasoning as irrelevant to any real-world decision making" (pp. 213–214). Across STEM fields, students may be needlessly marginalized by instruction that portrays ways of knowing as above the influence of context and free from value, putting it at odds with their personal cultural self-identity (Malcom and Feder, 2016). Textbook STEM education, free of discourse and culture, gives students a false impression of actual STEM practice.

In contrast to the culture-free myth, ethnographies examining practices in STEM fields, observed in the context of labs, field work, and conference activities, reveal a strong culture with specific language, norms, and practices held by an elite class of knowledge producers (e.g., Woolgar and Latour, 1986; Traweek, 1990). Uncovering and exploring the cultural dimensions of STEM is important for teachers and students because they foster students' connections to STEM and how they view themselves as learners in those fields. This in turn affects their efforts and academic achievement (Malcom and Feder, 2016). STEM teachers, in an attempt to transmit an objective, culture-free positivist notion of science actually promote a culture foreign to the students that is socially and intellectually distant from the students it is intended to help (Brickhouse, 1990; Lederman, 1992). Barrett and Nieswandt (2010) found that pre-service teachers self-identified strongly within their respective disciplinary group. As such, teachers in this group demonstrated resistance to take up "non-scientific" issues, a characteristic that did not alter throughout their teacher preparation program. It is evident that when faced with teaching SSI, new teachers may struggle to reconcile the disparate views of traditional classroom STEM learning and the SSI framework, which may result in open and often persistent resistance to SSI integration.

The second way that a presumption of appropriateness of value-free science is a problem is that it runs counter to the very essence of SSI as issues-based education. The goal of SSI teaching is to prepare students to deal thoughtfully with scientific issues as they exist in context. Furthermore, SSI are defined as issues for which science alone cannot impose resolution; ultimately only a value judgment can bring closure. Thus SSI classrooms are ideally places where the limits of scientific knowledge are intentionally examined (a goal explicitly supported in the Next Generation Science Standards). These classrooms are learning spaces where boundaries between disciplines are meant to be crossed and explored rather than avoided. Gieryn (1999), in presenting his seminal case studies on the "cultural boundaries" that demarcate science from non-science, wrote that

[p]utatively factual explanations or predictions about nature do not move naked from lab or scientific journal into courtrooms, boardrooms, newsrooms, or living rooms. Rather, they are clothed in sometimes elaborate representation of science—compelling arguments for why science is uniquely best as a provider of trustworthy knowledge, and compelling narrations for why my science (but not theirs) is bona fide" (p. 4).

In other words, any such borders are cultural accomplishments. For the lay person needing to engage with science in order to solve a problem that resides in large part *outside* of science proper, it makes little sense to exclude instances of "elaborate representation" from the curriculum. Effective SSI teachers do not presume that students will learn how to put "ready made" science (Latour, 1987) back into the contexts that have been stripped away by an education that has adhered to a firmly bordered science curriculum.

Another issue stems from resistance to ideological change or resistance to teaching for diversity. This is defined as the resistance to changing one's beliefs and value system (Rodriguez, 2005). Prospective teachers who show resistance to ideological change might believe that all students need only to work hard enough to be successful in science or mathematics or in life in general. They may also believe that students' gender, ethnic backgrounds, socioeconomic status, and language abilities, do not matter with regard to academic success. This "boot straps" mentality can present a major stumbling block in attempting to prepare STEM teachers to teach for diversity using more inclusive or culturally relevant strategies, like integration of the SSI framework, because it undermines the

need for teachers to be culturally responsive. Teachers may demonstrate this resistance not because they disagree with this orientation, but instead because they may lack the awareness, support, confidence, or knowledge and skills to implement socially relevant curriculum and culturally responsive strategies (Rodriguez, 2005).

Teachers' conceptions of SSI

According to Nuangchalerms (2009), it is important that pre-service teachers develop their own conception of SSI-based pedagogy to help their students understand the criteria of real science. Sadler et al. (2006) indicated that, while a great deal of diversity exists among teacher perspectives regarding ethics in science and science teaching, shared views exist on a variety of topics. Some educators have argued for the explicit consideration of the social contexts of the nature of science, even if such consideration reduces focus on some content, to provide an opportunity to "view science as a social enterprise embedded in a community of scientists" (Zeidler et al., 2002, p. 361).

Implementing SSI requires teachers to consider many different factors including how social values influence content, the epistemic values of reliable and productive scientific practice, and ethical questions raised as a result of scientific progress. The acknowledgment and understanding of how science and ethics are interdependent necessarily influences how teachers conceptualize SSI in their classrooms (Sadler et al., 2006). Specifically, research has shown that teachers implementing SSI recognize that "modern, democratic societies demand an informed populace capable of making decisions on controversial, value-laden issues" (Sadler et al., 2006, p. 362) and "SSI serve as effective means of relating science to students' lives" (p. 362). SSI are recognized for their potential to promote scientific literacy and to create an authentic, humane image of the processes of science, important tools for an informed society regarding critical decision-making regarding socioscientific issues (Ries and Galvão, 2009). According to Sadler et al. (2006) teachers tend to believe that the primary goal of integrating SSI and ethics into science was to promote student consideration of their own values and thus they should not impose their own values on students. A majority of the teachers participating in their study stated the belief that both sides of an issue were necessary when dealing with controversial topics, and that they avoided sharing personal beliefs for a variety of reasons (i.e., to avoid being perceived as trying to advance a personal agenda or to avoid legal ramifications). Teachers' personal knowledge of SSI being incorporated into the classroom enabled them to provide foundational support of social issues being developed and debated and clarity on the ethical values attached to SSI. Introducing SSI teaching to the STEM classroom can be difficult as it requires that teachers advance their own scientific literacy to better understand the issues that they incorporate to provide a well-rounded teaching environment (Nuangchalerms, 2009).

Institutionally speaking, many factors affect what teachers choose to do, including teachers' conceptions regarding accepted curriculum being the driving force regarding the concepts taught and means of assessment (Yerrick et al., 1997). Teachers may not recognize how SSI align with accepted curriculum and so constrain their choices to more traditional pedagogies, avoiding depth of coverage for breadth in topics covered. Teachers may avoid discussing controversial issues out of fear of complaints from students' parents or the sense of lack of control during classroom discussions (Ries and Galvão, 2009). This latter constraint reflects a lack of management skills related to classroom discussions and a lack of knowledge on the SSI. For teachers to be proficient at incorporating controversial SSI topics to address the nature of science and to improve reasoning skills, the teachers must be knowledgeable and experienced in this area (Zeidler et al., 2002). Other constraints to SSI implementation include time limitations, lack of administrative support, and pressures of standardized testing (Sadler et al., 2006; Yerrick et al., 1997), yet teachers who successfully incorporate SSI treat these as minor inconveniences rather than serious impediments. Others are more resistant to classroom implementation of SSI. Such resistance stems from numerous sources and is discussed in detail in upcoming sections.

Building new curriculum and adopting new repertoires of instruction

It is important that, when considering the purposes of STEM education, the goals, form, and function are aligned. Rudolph and Horibe (2016) sought to make explicit what is meant by teaching science "for civic engagement" and found that there are two basic ways in which the public interacts with science: how science is used to form policy and to a lesser extent how the conduct of science itself is to be supported, both through allocation of public resources and its accountability through regulation. They further pointed out that any notion of how science education should be done must reference the actual "avenues of engagement" that people actually have access to. To that point they reference Ryder's (2001) notion of functional scientific literacy. Ryder analyzed case studies of non-scientists engaging with institutional science, either directly with scientists or with representations of science such as media reports. He found that what really constitutes "functional literacy" is an ability to make sense of how science is represented in mass communication, an understanding of the epistemology of science (Ryder, 2001), and to a lesser but non-trivial extent the sociology of science itself or the notion that scientists work in a community of colleagues where they argue with each other toward establishing stable claims. It is important to note what he finds is *not* so crucial: an encyclopedic knowledge of scientific facts. Layton et al. (1993) performed a study with similar results. Lemke (1998) contended that learning about natural and technological phenomena includes engaging students in the kinds of patterns of action that scientists use in their work in meaningful ways. Duschl et al. (2007) identified the scientist's central activity as "argument in communities of practice for the purpose of persuading colleagues of the validity of one's own ideas and the ideas of others," (p. 187).

Researchers have argued that if scientific literacy is indeed a central and important goal of STEM education, “then scientific literacy must entail, at least in part, the ability to thoughtfully negotiate SSI and contribute to discourse regarding these topics” (Sadler et al., 2006, p. 354). For students, aspects of science discourse include the ways they construct scientific knowledge and make meaning from observation and participation in scientific processes (Johnson, 2011). However the most effective means of doing this are still being explored. According to Zeidler et al. (2005), the framework for teaching SSI includes four important pedagogical areas; (1) nature of science issues, (2) classroom discourse issues, (3) cultural issues, and (4) case-based issues (p. 361), that come together to inform teaching and promote the development of functional scientific literacy among students. While this framework points to four dimensions of curriculum-building work and classroom instruction that SSI teachers must attend to, they in turn can also be seen through the lens of ideological commitment. It is important to be specific about what SSI teaching entails when questioning whether teachers see its value because while “science literacy for all” is an easy mantra to profess; this consensus that “literacy” should be pursued tends to break down once we consider the kinds of pedagogy that would entail. Genuine scientific argument is rarely seen in classrooms. Instead, tacit turn-taking is often the primary means of communication in the classroom. Several factors influence the classroom discourse and limit teachers’ use of scientific argument. Many teachers are uncomfortable with argument and both teachers and students are often unable to distinguish between scientific argument and everyday argument (Duschl et al., 2007). Teachers may find difficulty in connecting claims to evidence and reasoning in discussing SSI cases. This has major implications in that teachers implementing SSI to foster functional scientific literacy must model the desired discourse practices (Johnson et al., 2020b). Nevertheless, participation is important. When curriculum presents students with challenging, socially relevant new knowledge, it provides the opportunity to become active participants in the community and engage in meaningful dialog (Rodriguez and Berryman, 2002). Fortunately, directed coursework and professional development can provide an avenue for perspective teachers with the resources and experience to develop the necessary skills for effective SSI implementation (Macalalag et al., 2019).

Providing teachers with firsthand experience in culturally relevant cases and familiar content allows for deep engagement in argumentation. This can build a foundation for application to teachers’ future instruction, allowing them to better align selected cases to student interests and backgrounds (Johnson et al., 2020b). One way that the SSI movement differs from prior efforts to infuse real-world applications into curricula and instruction is the “explicit attention to the ethical aspects of social issues with conceptual, methodological, and/or technological ties to science (Sadler et al., 2006, p. 354). SSI embeds STEM content into widely recognizable social and political contexts. The context is central in that when the ethical aspects of selected social issues align with students’ background and interest, the content is never irrelevant in the first place. Content is positioned as a necessary part of understanding an issue rather than an end in and of itself. This empowers learners to access scientific content in a completely different way and makes the primary goal of learning to make sense of or solve an authentic, personal problem that is directly faced by students in their own communities. The value of SSI is that it can teach not just what science is, but also how science is done, why science matters, and how science impacts everyone.

Hospitality of school contexts

The decision to implement SSI as an approach to STEM instruction does not happen in isolated spaces. Teachers must navigate numerous factors within their school context that both support and discourage teachers’ use of SSI in the classroom. These factors impact whether or not a teacher uses SSI as a context for instruction, and if so, influences the cases which teachers select to include in their curriculum (Hancock et al., 2019). Factors such as climate, schedules, high stakes testing, mandated curriculum standards and various school stakeholders’ philosophical ideals about the purpose of education all converge to impact teachers’ use of SSI at various levels including the classroom, school, and community.

One major factor cited by teachers as a barrier to implementing SSI is their perception that students will develop misconceptions of STEM content, thus negatively impacting learning outcomes (Aivelo and Uitto, 2019). Often because of this fear, teachers tend to shy away from SSI altogether or relegate their use of SSI to the end of a unit or article if time allows (Aivel and Uitto, 2019; Wong et al., 2011). This notion that “content” must be delivered is hard, or maybe impossible, to get away from when courses are tied to a high stakes test. Testing can become a bludgeon that enforces that the “delivery” task must be accomplished before SSI can happen.

Participants in a study conducted by Hancock et al. (2019) cited a focus on high stakes testing within their school as a barrier to their implementation of SSI even after a workshop guiding them to develop standards aligned lessons. Multiple studies with SSI case-based instruction have found that students tend to make progress on standards-based and standardized science assessments through engagement in SSI (Klosterman and Sadler, 2010). Furthermore, research supports the use of SSI cases to improve students’ abilities in evidence based arguments and critical thinking skills, as well as their understanding of both science concepts and the nature of science (Pinzino, 2012).

Directed course work and professional development can influence teachers intentions to implement SSI (Macalalag et al., 2019), but even when teachers do intend to use SSI cases in their classrooms they encounter challenges such as the need to use common curriculum materials and assessments, and the need to follow the same curriculum map and pacing guide as other teachers with whom they work. Hancock et al. (2019) found, however, that when working as part of a professional learning community team, these issues could be navigated and teachers on the team were able to find ways to include SSI within the confines their school context presented.

Firsthand experience with SSI cases is also an important factor in teachers' implementation of SSI. Through engaging directly in SSI, teachers gain knowledge and experience in the process of SSI implementation, yet they will engage most deeply in issues that they are interested in or have experience with (Johnson et al., 2020b). In a study conducted by McGinnis and Simmons (1999) inservice teachers engaged in a variety of SSI topics themselves before selecting and planning how they might implement them in their own classrooms. Findings revealed that teachers identified non-taboo issues as those that they felt comfortable teaching and cited their job security being threatened as a reason to stay away from more personally relevant cases, such as clean water in their building. Teachers also identified themselves as outsiders of the local school community, thus decreasing their willingness to teach topics they view as controversial to the community, despite seeing the value in such topics. Teachers often steered away from teaching that would result in some action being taken by students in response to controversial topics (McGinnis and Simmons, 1999).

Yet scholars such as McAvoy and Hess (2013) argue that avoidance of politics constitutes a missed opportunity to learn the necessary civic skills of deliberation on polarizing topics. Therefore controversial socioscientific issues are precisely the cases that teachers should include in their courses. Schools are important venue for learning to make decisions across different perspectives (Parker, 2003) because they can bring together diverse stakeholders. STEM classrooms, rather than being sites of uniform purpose meant only to prepare future STEM professionals, are likely to be some of the only places in which students can be exposed to more diverse beliefs and views than their immediate social circles (McAvoy and Hess, 2013). In light of this factor, and the likelihood that students are still developing their own political identity and therefore less likely to be politically engrained in ideas, the classroom is the ideal place for students to practice discussing and deliberating on controversial issues. On the contrary, teachers are more likely to be resistant to engage their students in such topics especially in politically polarized times (McAvoy and Hess, 2013).

Developing teachers' pedagogical content knowledge in SSI

Despite the challenges outlined in the preceding sections, SSI implementation can be fostered and maintained. Directed course work and professional development can develop teacher knowledge necessary for effective SSI implementation. STEM teachers who teach using SSI should include the following components in their lessons: (a) identify the issue, (b) explore and explain the underlying scientific phenomena, (c) engage in scientific modeling, (d) consider system dynamics, (e) employ reflective skepticism, (f) compare and contrast multiple perspectives, and (g) elucidate their own position or solution (Sadler et al., 2019). The pedagogical content knowledge (PCK) framework can provide a lens for understanding the requirements for the development of teachers' in planning, teaching, and reflecting on SSI (Bayram-Jacobs et al., 2018) as contexts for learning STEM concepts like arguments on global warming (Albe and Gombert, 2012), scientific literacy (Tal and Kedmi, 2006), and citizenship education (Barrue and Albe, 2013). According to Shulman (1986), PCK is the knowledge teachers must have within a discipline that is essential for them to effectively plan and implement teaching methods in order to help learners of various levels and backgrounds learn concepts and skills during instruction. PCK in general, and PCK for teaching SSI, includes several subdomains. Knowledge about the curriculum includes a teacher's awareness of the curriculum goals, objectives, and the vertical alignment and progressions of students' learning (Magnusson et al., 1999; Bayram-Jacobs, 2019). A teacher's knowledge about curriculum may come from state and national standards documents and curricular programs being used (Magnusson et al., 1999). Bayram-Jacobs et al. (2019) included the teacher's thinking about the importance for students and the learning objectives within lessons in this part of a teacher's PCK for SSI. In a study with inservice teachers, teacher PCK for SSI curriculum was demonstrated through the selection of controversial case-based issues (Macalalag et al., 2019). Teachers cited raising environmental awareness and social responsibility as their purpose in using the SSI cases which they selected.

In addition to knowledge of the curriculum, a teacher's PCK for SSI must also include knowledge of students' understanding. This includes an awareness of students' background knowledge and how students generally understand specific science concepts, the common misconceptions and preconceptions they may hold, and strategies to help students' learning move forward (Magnusson et al., 1999). Learning about students' backgrounds is especially important in regards to teachers' selection of SSI cases, so that teachers can align SSI cases to students' lives and make them personally relevant (Saunders and Rennie, 2013; Yerrick and Johnson, 2011). The moral and ethical reasoning involved in SSI teaching is what sets it apart from other orientations to teaching science (Zeidler, 2016). Saunders and Rennie (2013) suggest the use of an ethical framework to help support students' thinking throughout this process. Tal and Kedmi (2006) suggested continuous feedback between the teacher and students was important in SSI cases. Bayram-Jacobs et al. (2019) found that teachers with strong PCK tend to have a strong connection between knowledge of students' understanding and knowledge of instructional strategies.

In terms of knowledge of assessments, the teacher of SSI must know what, when and how to use suitable assessments in order to support learners during their exploration of SSI. For instance, in a study describing an Earth science SSI unit on beach sand replacement (Dolan et al., 2009), assessment was based on how students were able to engage in argumentation in order to provide both their scientific knowledge and personal beliefs to protect and restore the beach. Teachers may choose to assess individual or small groups of students' arguments using criteria such as the number of justifications, evidence provided, and counterclaim and rebuttals (Tal and Kedmi, 2006). Teachers must develop and apply their PCK on assessments in order to support students' learning of SSI. Teachers must be able to create a learning environment and assessment strategies in order to monitor and to support students' knowledge development in STEM, their ability to work with and to effectively engage in argumentation with other students, and

their ability to apply concepts to solve real world problems. This learning environment may include a continuous cycle of thinking and discussing, feedback, and reflection (Tal and Kedmi, 2006).

Finally, a teacher's knowledge of instructional strategies includes a teacher's ability to make appropriate choices about teaching and learning strategies in incorporating SSI (Magnusson et al., 1999). This is strongly connected to the teacher's knowledge of student understanding and assessment. A teacher of SSI must be able to incorporate a variety of teaching strategies that allow students to explore and explain the underlying scientific phenomena, engage in scientific modeling, employ reflective skepticism, compare and contrast multiple perspectives, and elucidate their own position or solution, which are several essential components of SSI (Sadler et al., 2019). As the teacher assesses students' evidence based arguments, they gain a sense of students' understanding and difficulties and use this to plan appropriate strategies to move students forward. The use of case-based strategies can provide a context for development of informal reasoning, such as Topcu et al.'s (2011) examples with human cloning, gene therapy and global warming. Minken et al. (2020) studied inservice teachers' use of multiple perspectives as an instructional strategy and found that although this is an important strategy for argumentation in SSI, teachers infrequently used it in their lesson plans.

Studies of course work and professional development models have suggested ways to educate and prepare both preservice and inservice teachers to implement SSI (Macalalag et al., 2019; Zeidler, 2016; Yerrick et al., 1997; Rodriguez, 2005). In several of these studies, teachers acted as learners to engage in scientific practices, such as evidence-based reasoning, scientific skepticism, and exploring connections between science and culture, through participation in selected case-based issues. Through coursework and professional development opportunities, teachers can engage in scientific practices themselves. In order to teach SSI, experiences in developing evidence-based reasoning are critical. Often, when teachers engage in evidence based reasoning, they cite vague evidence and lack a connection between their claim and the evidence suggested (Macalalag et al., 2019). Experiences in developing arguments centered on SSI cases can be a means to develop teachers' reasoning (Macalalag et al., 2019). Johnson et al. (2019) also found that teachers lack cohesion between claims and evidence in scientific arguments and suggest that this may be due to lack of experience in this type of communicating. As Michaels and O'Connor (1990) point out, if strategies and norms for participating in science discourse like argumentation are not actively pursued and promoted in traditional classrooms, they rarely develop on their own. Teachers who have never experienced this type of argumentation themselves will be unfamiliar and uncomfortable implementing it in their classrooms. Yet, course work and professional development can help. Coursework can provide avenues for teachers to evaluate the sources of evidence and information. In the works of Macalalag et al. (2019) and Kolsto (2006), teachers were skeptical of sources provided as they searched for evidence and examined the motivations and possible biases of the authors as part of their discussions of SSI. Opportunities for evidence based reasoning with scaffolded support are necessary for teachers to develop these abilities (Johnson et al., 2019). A clear understanding of teachers' abilities in these areas can also assist in the development of targeted experiences for professional development and coursework (Johnson et al., 2019).

As we have illustrated, resistance to change in teaching practice may stem from many sources. SSI integration can provide a powerful tool for teaching in culturally relevant ways as it allows teachers to gain a deeper understanding of students' conceptual frameworks during discussions of socioscientific issues (Zeidler et al., 2002). However, prospective teachers may purposely refuse to teach for diversity and understanding for a variety of reasons (Rodriguez, 2005). School policies, preservice training, strict accountability, rigorous state assessments, teacher socialization, and mandated curriculum and assessment may influence teachers so much that they resist thinking about content and teaching in any other way (Yerrick et al., 1997). This type of resistance to pedagogical change or resistance to learning to teach for understanding results from teachers' avoiding, refusing, or feeling unable to change their perceptions of what it means to be an effective teacher (Rodriguez, 2005), and is an ongoing challenge in preparing STEM educators. Educators who demonstrate this form of resistance may prefer lecture and individual student work, providing the students the content first as a de facto prerequisite before they can be allowed to do any kind of application or experiment. These teachers may view science teaching as the transmission of lists of concepts and students as passive recipients (Yerrick et al., 1997). There is also the possibility that teachers may show resistance to pedagogical change because they lack the knowledge, skills, and confidence to move away from transmissive models of teaching which they themselves have experienced throughout their education (Lortie, 1975). As Yerrick et al. (1997) point out, the ubiquitous adoption of transmissional modes of teaching is especially troubling since it conflicts so strongly with methods shown to be effective for teaching for the ever increasing diversity within schools.

Numerous studies have shown that, while the forms of resistance described above are all too common, they can be overcome in preparing teachers to teach for diversity in inclusive and culturally responsive ways (Rodriguez and Kitchen, 2005). In particular, SSI provides a strong framework for engaging students and teachers in meaningful and relevant scientific discourse in the development of functional scientific literacy (Zeidler et al., 2005) and although it can be difficult for teachers to engage in arguments around SSI, coursework and professional development can provide a means for them to do so (Macalalag et al., 2019; Nuangchalerms, 2009). Varelas et al. (2018) examined an intervention intended to raise awareness among pre-service teachers regarding environmental racism. Their work showed that pre-service teachers began to see their role as more than just a science teacher as they expanded their views of the ways science is relevant in peoples' lives. Macalalag et al. (2019) indicated positive views among in-service and pre-service teachers regarding teaching controversial and complex case-based SSI lessons following completion of a STEM certification endorsement program founded in the SSI framework. Participating teachers indicated raising environmental awareness, teaching social responsibility, and teachers' interest on SSI topics as reasons for their views. This study attributed the development of the cultural issues component of SSI to teachers' field experiences in Pennsylvania, USA and in Sicily, Italy embedded within the STEM endorsement program, which included shifts on teachers' perceived cultural practices, reducing carbon dioxide, and teaching of SSI in their classrooms. In another study by Macalalag et al. (2017), following the methods course within the STEM endorsement program, more teachers identified connections between science and engineering and demonstrated more detailed and specific

understandings of STEM concepts and processes based on their experiences with SSI. Their experiences and discussion of SSI within the course and field experiences provided them a template for integrating SSI into their own teaching. Following the course their focus shifted to actual implementation as opposed to simply identifying the need.

Conclusions

Incorporating SSI into STEM classrooms provides a way to teach all students about STEM content because it situates STEM content in contexts that are meaningful to them, however this asks STEM teachers to teach in ways that they are often ill-prepared for, unsupported in, and/or personally resistant to on ideological grounds. STEM teacher education and professional development has been shown to be effective and necessary in fostering SSI implementation, particularly at sites where STEM teachers are supported to work through the problems they are likely to face when enacting SSI teaching.

A first necessary step toward reform is to raise awareness of the ways that STEM impacts people. Varelas et al. (2018) examined an intervention intended to develop a consciousness among pre-service teachers about environmental racism. Their work showed that pre-service teachers began to see their role as more than just a science teacher as they expanded their views on the ways science is relevant in peoples' lives, sometimes in adverse ways.

To facilitate and maintain integration of SSI among pre-service and in-service teachers, teacher educators must provide a variety of experiences in which developing teachers directly participate in SSI from the students' point of view. In doing so, teachers will develop an extensive repertoire of SSI strategies and contexts, while also learning how to learn, develop, and implement their own SSI lessons focusing on contexts specific to their classroom (Johnson et al., 2020a). Experience with multiple SSI cases within a teacher preparation program will better prepare teachers to provide culturally relevant and engaging opportunities for their students to build understanding. Culturally relevant cases with familiar content allow for deep engagement in argumentation and application to teachers' future instruction, allowing them to better align selected cases to student interests and backgrounds.

Introduction

The rise of STEM education is highly influenced by political and business leaders related to concerns about shortages in the STEM workforce. For example, the National Governors Association (NGA) (Toulmin and Groome, 2007) argued,

America's economic growth in the 21st century will be driven by our nation's ability to generate ideas and translate them into innovative products and services. A strong consensus is emerging among scientific, business, and education leaders that America's ability to innovate and compete in the global marketplace is directly tied to the ability of our public schools to adequately prepare all of our children in STEM (p. 4).

Arguments related to the STEM workforce have similarly propelled countries around the world to establish STEM policies and initiatives designed to improve the quality of STEM education (Freeman et al., 2014). Other equally important arguments for global STEM initiatives are more equitable education, poverty reduction, and increased STEM literacy and awareness (Freeman et al., 2014; National Research Council [NRC], 2014).

Concurrently, professional societies, such as the American Society for Engineering Education (ASEE) and the National Academy of Engineering (NAE), promoted K-12 engineering and set the stage for a more integrated approach to STEM education. In *Engineering in K-12 Education: Understanding the Status and Improving the Prospects*, the NAE and NRC argued that, "in contrast to science, mathematics, and even technology education, all of which have established learning standards and a long history in the K-12 curriculum, the teaching of engineering in elementary and secondary schools is still very much a work in progress (NAE and NRC, 2009, p. 2). Rationales for the inclusion of engineering into the K-12 curriculum include: (a) engineering as a real-world context to motivate science and mathematics learning, and (b) engineering design tasks as a context to promote the development of 21st century skills (Brophy et al., 2008; Hirsch et al., 2007; Koszalka et al., 2007). Ultimately, engineering is viewed as "a catalyst for integrated STEM education" given the "considerable potential value, related to student motivation and achievement, in increasing the presence of technology and, especially, engineering in STEM education ... in ways that address the current lack of integration in STEM teaching and learning (NAE and NRC, 2009, p. 150)."

The subsequent release of the *Framework for K-12 Science Education* (NRC, 2012) and *Next Generation Science Standards* (NGSS) (NGSS Lead States, 2013), as well as parallel international policies (e.g. Commonwealth of Australia, 2015; Department of Education, 2009), created demand for the rapid development of professional learning opportunities and quality STEM curricula for K-12 teachers. One challenge has been in simultaneously developing curricular components for use in K-12 classrooms while also conceptualizing and actualizing what makes for high-quality integrated STEM instruction. This paper addresses this challenge in reform efforts by describing the development and implementation of integrated STEM curricula in K-12 classrooms.

Brief history of integrated STEM curriculum development

New curricula are considered central to education reforms (Powell and Anderson, 2002), and these curricula may be developed as a mandated national curriculum or as in the United States through state, school, and teacher-level decisions. In the case of integrated STEM education, it is important to acknowledge that interdisciplinary approaches to curriculum development is not a new idea. Researchers have argued for decades that meaningful learning requires that students have opportunities to learn through the development and application of knowledge and skills to real-world problems (e.g. Beane, 1995; Brooks and Brooks, 1993; Czerniak et al., 1999; Hirst, 1974; Jacobs, 1989). Given that real-world problems are inherently interdisciplinary in nature, teaching approaches anchored by real-world problems require integrated approaches. For example, Problem-Based Learning (PBL), which originated in medical education, uses complex real-world problems to promote student learning of concepts and principles by proposing possible solutions to the problem (Hung et al., 2008). Although PBL can be used across all disciplines, its approach to teaching and learning is well suited to contexts that require students to draw upon STEM knowledge to solve problems.

Integration within the STEM disciplines has historically focused on the integration of science and mathematics (e.g., Berlin and White, 1995; Davison et al., 1995; Huntley, 1998), with little attention to technology and engineering (Bybee, 2010; Hoachlander and Yanofsky, 2011). However, the recent addition of engineering into national science standards (NRC, 2012; NGSS Lead States, 2013) has led to a renewed focus on integration. Engineering by definition requires the application of knowledge from science, mathematics, and technology to solve real-world problems through engaging in an engineering design process (Brophy et al., 2008; Douglas et al., 2004). Prior to calls from educational reforms to explicitly include engineering into science standards, a review of K-12 engineering curricula (NAE and NRC, 2009) found that while there are implicit connections between engineering and the disciplines of mathematics, science, and technology, existing K-12 engineering curricula do not clearly and explicitly integrate across the STEM disciplines. The review found a wide variety of curricular approaches to K-12 engineering with the only strong commonality being the engagement of students in the engineering design process; “Virtually all of the curricula present a paradigm for designing solutions to problems that include a cyclical pattern of steps” (NAE and NRC, 2009, p. 82). While engineering was often used to contextualize science learning with a real-world problem, rarely were students asked to engage in scientific inquiry “to generate data that could then be used to inform engineering design decisions” (NAE and NRC, 2009, p. 157). Connections to mathematics were found to be weak and limited to gathering, organizing, analyzing, interpreting, and presenting data, additionally, technology was most often represented simply as the product of engineering. The release of the *Framework for K-12 Science Education* (NRC, 2012) and the NGSS (NGSS Lead States, 2013) led to a critical need for both quality integrated STEM curriculum and professional development for K-12 teachers.

Integrated STEM curriculum development and implementation: the case of *EngrTEAMS*

One response to this demand was the National Science Foundation (NSF) funded Mathematics and Science Partnership grant, *EngrTEAMS: Engineering to Transform the Education of Analysis, Measurement, and Science* (DRL #1238140). *EngrTEAMS* aimed to increase grade 4–8 student learning of science concepts, as well as the mathematics concepts related to data analysis and measurement, by using an engineering design-based approach to curricular development and teacher professional development. Each summer of the *EngrTEAMS* grants, teachers from five partner school districts attended a three-week summer professional development (PD). The PD included learning opportunities for teachers related to STEM teaching and learning, including integration work related to a specific science content area (earth science, life science or physical science topics) relevant to their teaching assignment. During the PD, small teams of teachers developed new integrated STEM units with the support of a graduate student coach. Teachers piloted their curriculum in an informal summer camp on a university campus and used this experience to revise their curriculum before implementing the unit in their respective classrooms during the academic year. Final revisions to the integrated STEM units were made at the end of each academic year. By the end of the project, a total of 87 teachers participated in writing 50 unique integrated STEM curricula.

Need for an integrated STEM curriculum framework

Even after the implementation of the NGSS in the United States and related global policies, there remains disagreement on focus, models, and effective approaches for integrated STEM instruction (Bybee, 2010; Moore et al., 2020). In spite of these global policy calls for STEM education, there is no consensus on a theoretical or practical definition of integrated STEM to guide curriculum development. Based on common implementations of STEM education, Bybee (2010) outlined a continuum of models ranging from STEM disciplines as completely separate and disconnected to full integration of all four STEM disciplines, more akin to interdisciplinary and transdisciplinary models described by Vasquez et al. (2013). While disagreements still exist, there is a developing consensus around features indicative of quality integrated STEM that can be used to guide curriculum development (Moore et al., 2020). Consensus features of quality integrated STEM include: (a) using real-world contexts to engage students in authentic and meaningful learning (Kelley and Knowles, 2016; Moore et al., 2014a; Sanders, 2009), (b) using student-centered pedagogies (Kelley and Knowles, 2016; Moore et al., 2014a), (c) supporting the development of 21st century skills such as creativity, collaboration, communication, and critical thinking (Honey et al., 2014; Moore et al., 2014b), and (d) making the connections between STEM disciplines explicit to students (English, 2016; Herschbach, 2011; Honey et al., 2014; Kelley and Knowles, 2016; Moore et al.,

Table 1 Six tenets of the Framework for Integrated STEM.

Tenet	Tenet description	Supporting literature
1	Quality STEM integration contextualizes learning for students by engaging students in motivating and authentic problems	Breiner et al. (2012); Brophy et al. (2008) Brown et al. (2011); Carlson and Sullivan (2004); Frykholm and Glasson (2005); Kelley and Knowles (2016); Kennedy and Odell (2014); Labov et al. (2010); Rinke et al. (2016); Sanders (2009)
2	Integrated STEM curricula must include mathematics and/or science content as main objectives of the activity.	Harris and Felix (2010); Fortus et al. (2004); Mehalik et al. (2008)
3	Students develop and apply mathematics and science content by engaging in the engineering design process .	Brown et al. (2011); Dym et al. (2005); English (2016); Herschbach (2011); Honey et al. (2014); Kelley and Knowles (2016); Kennedy and Odell (2014); Labov et al. (2010); Rinke et al. (2016); Sanders (2009)
4	Engineering problems have multiple solution pathways and engineers use evidence-based reasoning to iteratively improve their design solutions providing opportunities for students to learn from failure through redesign	Dym et al. (2005); Morrison (2006); NRC and NAE (2009), NRC (2012)
5	The implementation of integrated STEM requires the use of student-centered pedagogies such as inquiry, discovery, and engineering design that help students develop and apply knowledge in a manner that deepens conceptual understanding	Breiner et al. (2012); Furner and Kumar (2007); Kelley and Knowles (2016); Kennedy and Odell (2014); Labov et al. (2010); Rinke et al. (2016); Sanders (2009); Smith et al. (2005); Stinson et al. (2009)
6	Quality integrated STEM curricula emphasizes teamwork and communication .	Brown et al. (2011); Carlson and Sullivan (2004); Dym et al. (2005); Honey et al. (2014); Kennedy and Odell (2014); NRC and NAE (2009); NGA (2010); Rinke et al. (2016); Smith et al. (2005)

2014a, 2014b). Given the prominence of engineering within STEM policy documents (e.g. NRC, 2011, 2012; NGSS Lead States, 2013), an engineering context or problem is often central to integrated STEM curriculum (Bryan et al., 2016; Hmelo et al., 2000; Mehalik et al., 2008; Moore et al., 2014a; Sadler et al., 2000).

Specifically, the teachers' curriculum writing within *EngrTEAMS* was guided by two frameworks for STEM integration (Moore et al., 2014a, 2014b), as well as by state science standards, which included engineering at the time of the project. The framework for integrated STEM instruction (Moore et al., 2014a) includes six tenets to guide integrated STEM curriculum development (Table 1). The *Framework for Quality K-12 Engineering Education* (Moore et al., 2014b) describes nine key indicators, which expand upon the framework for STEM integration and provide more specific descriptions for the integration of engineering content and practices (Table 2). The indicators in the *Framework for Quality K-12 Engineering Education* articulate quality features for the full

Table 2 Framework for quality K-12 engineering education.

Key indicator	Description
Process of design (POD)	Engineering design process
Problem and background (POD-PB)	Identifying an engineering problem in need of a solution—includes researching the problem, participating in learning activities to gain background knowledge, and identifying constraints
Plan and implementation (POD-PI)	Developing and implementing a plan for a design solution to an engineering problem—includes brainstorming, developing multiple solutions, and evaluating pros and cons of multiple solutions
Test and evaluate (POD-TE)	Generating a testable hypothesis/question and designing experiments to evaluate them—includes data collection and analysis for use in redesign
Apply science, engineering, and mathematics (SEM)	Applying mathematics or science in the context of solving engineering problems
Engineering thinking (EThink)	Applying independent, reflective, and metacognitive thinking to improve solutions and learn from failure—includes systems thinking, creativity, optimism, perseverance, and innovation
Conceptions of engineers and engineering (CEE)	Developing an understanding of what engineers do—includes work driven by client needs, design under constraints, and learning about various engineering disciplines
Engineering tools (Etool)	Developing proficiency using techniques, skills, processes, and tools used in engineering
Issues, solutions, and impacts (ISI)	Understanding the impact of solutions in a global, economic, environmental, and societal context
Ethics	Understanding ethical considerations inherent in engineering - includes responsibility to natural and client resources; effects of a design on public health and safety; governmental regulations and professional standards; and integrity
Teamwork	Developing teamwork and interpersonal skills—includes participating in collaborative groups in a variety of roles
Communication related to engineering (Comm-Engr)	Developing technical writing skills and ability to communicate technical ideas in common language—includes symbolic and pictorial representations

Table 3 Alignment of Diggin' for Fools Gold curriculum with STEM curriculum frameworks.

	<i>Lesson description</i>	<i>Alignment to STEM frameworks</i>
1	Students are introduced to the engineering design challenge. Students review the engineering design process and engage in problem scoping as they discuss and identify relevant criteria and constraints.	Tenets 1, 5, and 6 CEE, POD-PB, teamwork
2	Students explore properties of magnets and magnetism through a series of laboratory stations.	Tenets 2,5, and 6 POD-PB, teamwork
3	Students explore how they can use an electromagnet to pick up magnetic materials and generate a list of variables that might impact the strength or performance of the electromagnet.	Tenet 2, 5, and 6 POD-PB, teamwork
4	Students carry out a guided inquiry activity to test the impact of the number of coils of the strength of the electromagnet. Students represent their data in graphical form and writing claims supported with evidence about the effect of coils on electromagnets.	Tenets 2, 5, and 6 POD-PB, teamwork
5	Teams choose another variable to test, create tables/visual displays to look for patterns in the data, and share their claims and evidence with the class.	Tenets 2, 5, and 6 POD-PB, teamwork
6	Using data from lessons 4 and 5, students design, build, and test an electromagnetic claw arm prototype, using their test data to justify their design decisions.	Tenets 3, 4, 5, and 6 POD-PI, SEM, Ethink, Comm-Engr, teamwork
7	Students redesign and retest their new designs with several different toys of different sizes. The students present their best design to the client describing the results of the tests, as well as the reasoning behind their design choices.	Tenet 3, 4, 5, and 6 POD-TE, SEM, Ethink, Comm-Engr

K-12 scope and sequence; it is not intended that all nine indicators be present in every unit or lesson, rather that students experience all of the indicators at some point in their K-12 education. Three of the indicators, Process of Design (POD), Science, Engineering, and Mathematics (SEM), and Engineering Thinking (ETthink) are considered the most central and should be included in all curricular units (Moore et al., 2014b).

An example of an integrated STEM curriculum that aligns with the above frameworks is *Electromagnetic Crane Arm*. This curriculum was developed by a team of three elementary science specialists as part of the *EngrTEAMS* project to be used in their fourth grade classrooms. In this curriculum, students are introduced to a fictitious client, Galactic Games, that is concerned that people are no longer playing their claw arcade game due to reports that these games are rigged. The students are asked to develop a prototype of an electromagnetic attachment for the arm that will be used in the game instead of the mechanical claw. Students learn about magnetism and electromagnetism through a series of guided inquiry science lessons and then apply their knowledge of science to the iterative design of a new electromagnetic attachment that meets the criteria and constraints set by the client. Mathematics is integrated as measurement, data analysis, and graphing. Technology is integrated both as the product of engineering and through the integration of instructional technology to support data collection and analysis. Details for each of the seven lessons and their alignment to the STEM frameworks are shown in Table 3.

Broad approaches to engineering integration

Crotty et al. (2017) analyzed the 20 integrated STEM curricula developed during the first year of *EngrTEAMS* to understand the curricular approaches to the integration of an engineering design challenge into science units. Three approaches to engineering integration were identified: (a) a culminating project where engineering was introduced only at the end of a science unit and aimed to require students to use their science knowledge, (b) implicit integration where the engineering design challenge provided context for the unit and was revisited as a culminating project at the end of the unit, and (c) explicit integration where the EDC not only provided context for the unit, but was purposefully revisited during each lesson leading up to the culminating EDC. Simply including an engineering design challenge as a culminating project produced significantly lower student learning related to engineering than when the engineering design challenge was also included at the beginning of the unit to frame the learning and revisited throughout the unit. Interestingly, no differences in student learning were found between implicit and explicit approaches, which suggests a more nuanced assessment of curriculum quality is necessary. While valuable in understanding the use of an EDC within a STEM curricular unit, this work did not assess the quality of the integration or coherence of conceptual development, which will be addressed in the following two sections.

STEM integration curriculum assessment

The STEM Integration Curriculum Assessment (STEM-ICA) (Guzey et al., 2016) was developed from the framework for integrated STEM instruction (Moore et al., 2014a) as a mechanism to evaluate integrated STEM curricula. The STEM-ICA is composed of nine items: (a) motivating and engaging context, (b) engineering design, (c) integration of science content, (d) integration of mathematics content, (e) instructional strategies, (f) teamwork, (g) communication, (h) assessment, and (i) organization. Each item in the STEM-ICA is rated on a 5-point scale from 0 to 4 (0: not present, 1: weak, 2: adequate, 3: good, 4: excellent). Table 4 provides some examples of the descriptive elements within each of the nine items, and the full version of the STEM-ICA can be found in the published paper (Guzey et al., 2016).

Table 4 Description of the STEM-ICA items.

<i>STEM-ICA item</i>	<i>Sample descriptive elements</i>
To what extent does the curriculum unit use a motivating and engaging context?	- allow students to draw on their personal knowledge and experiences? - engage and motivate students from different backgrounds? - provide a context with a compelling purpose.
To what extent does the curriculum unit allow students to learn engineering design by integrating an engineering design challenge?	- provide opportunities to apply engineering process in authentic situations? - require students to use engineering design processes? - allow students opportunities to learn from failure? - allow students to redesign? - require students to consider constraints, safety, reliability, risks, alternatives, trade-offs, and/or ethical considerations? - promote engineering habits of mind?
To what extent does the curriculum unit integrate science content needed to solve the engineering challenge and support in-depth understanding?	- integrate science concepts that are grade level appropriate? - require students to learn, understand, and use fundamental science concepts necessary to solve the engineering challenge? - promote coherent conceptual understanding of science?
To what extent does the curriculum unit integrate mathematics content needed to solve the engineering challenge and support in-depth understanding?	- integrate mathematics concepts that are grade level appropriate? Require students to learn, understand, and use fundamental mathematics concepts necessary to solve the engineering challenge? - promote coherent understanding of mathematical thinking?
To what extent does the curriculum unit support student centered teaching strategies?	- contains lessons and activities that are student-centered? - contain activities that require students to collect and analyze information or data before arriving at a solution? - engage students in argumentation and evidence-based reasoning?
How well does the curriculum unit enable students to develop teamwork skills?	- require students to collaborate with others? - build in instructional strategies that encourage positive team interactions?
How well does the curriculum unit enable students to develop communication	- require students to communicate science concepts and engineering thinking/engineering solutions/products? - include a requirement for using evidence to support claims and design decisions?
To what extent do the assessments and required assignments in the curriculum unit measure students' knowledge and skills?	- are closely aligned with the learning objectives and goals and content from the multiple disciplines of STEM? - provide students opportunities to produce evidence of understanding and abilities in different ways through performance tasks?
How well is the curriculum unit organized?	include activities/lessons that flow in a logical and sequential order so they build on each other?

The STEM-ICA was used to evaluate the integrated STEM curricula developed during the first year of *EngrTEAMS* (see [Guzey et al., 2016](#) for details). Two items, mathematics integration and communicating mathematics, science, and engineering thinking, were found to only weakly contribute to the overall quality of the STEM units. Additionally, none of the curricula scored highly for science integration. The STEM-ICA provides valuable insight regarding the level of integration of the STEM disciplines, but similar to challenges with [Crotty et al.'s \(2017\)](#) broad approach to assessing curriculum quality, it does not provide information about the coherence of the curriculum.

Conceptual flow graphics

Given the struggle to produce integrated STEM curricula with strong integration of science and mathematics ([Guzey et al., 2016](#)), new mechanisms are needed for both researchers and teachers to understand the nature of integration within curricula. A Conceptual Flow Graphics (CFG) offers a visual means to evaluate integration across the disciplines within a given curriculum. Further, these visual depictions offer a way to identify and assess curricular coherence. CFGs are developed by identifying the main content learning for the unit and each individual lesson, then mapping the degree of connectivity between the lessons and between each lesson and the main unit goal (see [Roehrig et al., 2021](#) for detail). [Fig. 1](#) provides an example of a CFG generated for the *Electromagnetic Crane Arm* curriculum (see [Table 3](#)). A bold black border around the content goals for a lesson indicate that there is an explicit connection to the EDC through a letter or memo from the client and a solid arrow show strong connectivity between lessons. Each lesson in the *Electromagnetic Crane Arm* unit is coherently connected, for example students cannot plan a prototype design for their electromagnetic arm attachment (Lesson 5) without understanding the impact of variables such as the number of coils, number and type of batteries, and wire gauge on the strength of an electromagnet. In contrast, [Fig. 2](#) shows a CFG for a curriculum where students are asked to design a means to prevent cross-pollination between fields of non-GMO and GMO corn. Pedagogical connections through teacher guidelines within the written curriculum that direct the teacher to remind students about the engineering design challenge and the client's needs are designated with a dashed black box around the lesson concepts. A dashed arrow represents a weak connection between lessons, and the absence of an arrow represents that there is no conceptual connection between lessons. In this curriculum, while the science lessons build conceptually on each other, there are minimal

Fig. 1 Conceptual flow graphic for the *electromagnetic crane arm* unit. A *solid arrow* represents strong conceptual connection between lessons or a lesson and the Engineering Design challenge. A *solid box* around a lesson represents a contextual connection to the client through curricular materials such as a client letter.

Fig. 2 Conceptual flow graphic for the *GMO corn* unit. A *solid arrow* represents strong conceptual connection between lessons or a lesson and the Engineering Design challenge. A *dotted arrow* represents weak conceptual connection between lessons or a lesson and the Engineering Design challenge. A *dashed arrow* represents a contextual connection between a science lesson and the Engineering Design challenge. A *solid box* around a lesson represents a contextual connection to the client through curricular materials such as a client letter. A *dashed box* around a lesson represents a contextual connection to the client to be made verbally by the teacher as suggested in teacher guidelines accompanying the curriculum.

connections between science lessons and the EDC. In other words, the students can propose solutions to the EDC without using any scientific content learned in the unit.

Roehrig et al. (2021) analyzed all 50 *EngrTEAMS* curricula (16 earth science, 15 life science, 19 physical science), through the use of CFGs. Of the 21 curricula that included strongly integrated and coherent lessons, as illustrated in Fig. 1, 18 were physical science curricula. Conversely, all of the life science curricula represented weak integration with coherence of the EDC with science lessons limited to providing information about the engineering context rather than content knowledge needed to develop design solutions. Similarly, all but one of the earth science curricula included engineering design lessons with, at best, weak integration between science and engineering lessons. As with other studies (e.g. Guzey et al., 2016; NAE and NRC, 2009), the CFG analysis revealed that mathematics concepts represented less than 10% of the main concepts to be learned in each lesson across all integrated STEM curricula. Aligning motivating and engaging engineering contexts with grade-level science and mathematics standards is not easy. Researchers have outlined a backward design approach (Wiggins and McTighe, 1998) where relevant STEM concepts are identified from analysis of an EDC (e.g. Chalmers et al., 2017) to generate curricular activities. However, if the relevant STEM concepts are not aligned with grade-level standards, teachers will be hesitant to adopt a curriculum that takes time from required content standards. For example, genetic engineering is a field that has myriad engaging topics, and while topics such as the polymerase chain reaction and gel electrophoresis are common applications of genetics knowledge in undergraduate courses (Phillips et al., 2008), they are beyond the expectations of a middle school or even high school science class.

Other important findings from the CFG analysis of integrated STEM curricula indicate the importance of maintaining connections to the EDC as a means to contextualize learning throughout the unit and explicitly connect science and mathematics learning to the engineering context. Two fruitful mechanisms to make the integration amongst the disciplines explicit are the use of client letters or memos and evidence-based reasoning; these mechanisms are often intertwined, as demonstrated below. Professional engineers produce design solutions to meet the needs of a client; thus, it is recommended that K-12 engineering lessons also focus on generating solutions for a client, mirroring the work of professional engineers (Brophy et al., 2008; Cunningham and Carlsen, 2014). In almost all *EngrTEAMS* curricula, a client letter was used to introduce the engineering design challenge and establish relevant criteria and constraints. In the strongly coherent and integrated curricula, there were frequent interactions with the client, including: (a) follow-up memos from the client, (b) sharing of prototypes, test data, and final designs with the client, and (c) opportunities to ask clarifying questions or get feedback from the client. Evidence-based reasoning, which will be discussed in more detail in the implementation section, was used as a specific form of communication with the client where students were expected to justify their design decisions with scientific and/or mathematical evidence (Siverling et al., 2019).

Considerations for selecting an engaging context

As already discussed, there is consensus that integrated STEM curricula should utilize authentic problems to contextualize students' learning (Kelley and Knowles, 2016; Moore et al., 2014a; Sanders, 2009). However, given the need to diversify the STEM fields (NSF, 2019), there needs to be careful consideration of the selection and representation of real world problems. For example, research suggests girls and students of color are more motivated by real-world problems that are people-oriented and focused on societal issues such as health, the environment, and social justice as opposed to more gendered engineering projects such as designing cars and rockets (Dare and Roehrig, 2020; Diekman et al. 2010; Leammukda and Roehrig, 2020).

Many engineering and integrated STEM curricula use global contexts in developing engineering design tasks. However, the use of contexts not centralized on the communities or lived experiences of the students can be problematic (Gruenewald, 2003). Keratithamkul et al. (2020) found that the use of contexts that ask students to design for a non-dominant culture can be problematic and lead to students developing deficit-based views of the people and places presented in the lesson, rather than the desired culturally competent views. Researchers have suggested a place-based (Semken and Freeman, 2008) or community-based approach (Melaville et al., 2006) to STEM curriculum development that situate learning locally and provide an opportunity for students to make a difference in their communities (Keratithamkul et al., 2020; Leammukda and Roehrig, 2020; Nadelson and Seifert, 2013).

Implementing integrated STEM curricula in K-12 classrooms

To date, little research has been published surrounding teacher and student learning related to integrated STEM, although research related to policy, curriculum, evaluation, and assessment has accounted for nearly half of STEM education-related publications (Li et al., 2020). As part of the *EngrTEAMS* project, several research studies have focused on the implementation of integrated STEM curricula. For instance, Dare et al. (2018) found that sixth grade physical science teachers struggled to make connections between the STEM disciplines. Teachers who used an implicit approach to integration noted that their students did not make connections between the science content and developing solutions to the associated EDC, and when students did not access and apply relevant content knowledge, they resorted to design by tinkering. The teachers with the highest quality lessons explicitly connected science content to engineering design decisions. This required students to develop a deep conceptual understanding of the science content; for example, simply knowing the definition of an insulator was not enough to purposefully select materials to effectively insulate a cooler. Successful teachers also provided multiple opportunities for students to explain how the science content informed their design solutions, both verbally and in writing. Successful implementation of integrated STEM curricula takes time and requires strong pedagogical skill in facilitating and supporting learning. Teachers in this study shared the constant dilemma of having to

decide how much support and guidance to provide students in their design work, balancing frustration and opportunities to problem solve and engage in creative thinking.

Dare et al. (2018) also found that teachers focused primarily on science and engineering, finding little time to explicitly include mathematics into their instruction. This minimization of including mathematics reflects teachers' conceptions of STEM as reported by Ring-Whalen et al. (2017) and Ring-Whalen et al. (2018), wherein mathematics was often treated as a means to an end or a tool only used to analyze data for science and engineering learning. Ring-Whalen et al. (2018) noted that the ways in which teachers conceptualized STEM education played a role in how curricular units were designed and implemented. Similarly, other researchers have reported that teachers' attitudes to STEM and associated reform-based teaching practices influence their implementation of integrated STEM (Thibaut et al., 2018).

Understanding integrated STEM implementation through student discourse

Given the focus of integrated STEM curricula on developing teamwork and collaboration skills, quality curricula call for students to engage in science and engineering practices in small groups. The prevalence of small group work in STEM education means that there is a critical need for implementation research to examine how students interact to construct knowledge and design solutions with their small groups, in addition to implementation research focused on the role of the teacher (e.g. Dare et al., 2018).

Several studies have explored the ways in which students use STEM disciplinary knowledge to justify their design decisions during the implementation of *EngrTEAMS* curricula (Guzey and Aranda, 2017; Mathis et al., 2016; Mathis et al., 2018; Siverling et al., 2019). Using audio-recordings of one small group in each of seven integrated STEM curriculum implementations, Siverling et al. (2019) identified 15 categories that describe how students generate and justify their design decisions throughout their small group work. Students used science content aligned with the curriculum under investigation, but also invoked science content not taught in the curriculum. Similarly, students used mathematics content both from within and outside the curriculum. Categories for justifying design decisions based on engineering principles included: (a) overall design, (b) material type, (c) material amount, (d) functionality (e) structure, (f) execution of design, (g) ease of use, (h) cost, (i) procedural step, and (j) aesthetics. Finally, students used their knowledge of and familiarity with existing technologies to justify design decisions. Results are mixed in terms of how students engaged in evidence-based reasoning during the engineering design process. Siverling et al. (2019) reported that all seven small groups used science from the curriculum and five small groups used mathematics from the curriculum in their design work. However, Guzey and Aranda (2017) found that small groups rarely used science in their justifications; rather they focused on cost as the primary factor for making design decisions. These mixed findings suggest that more work is needed to explore facets of curriculum and task design that afford opportunities for students to apply of science and mathematics knowledge during engineering design lessons. Other researchers have also found that students place an emphasis on cost and material limitations when engaging in engineering design tasks (e.g., English et al., 2013), suggesting that more detailed analysis of how constraints are integrated into integrated STEM curricula is needed. It is also noteworthy that Guzey and Aranda (2017) reported that the group that most often used science to justify their designs was explicitly prompted to do so by the teacher.

Given concerns about the under-representation of women and racial minorities in the STEM fields (NSF, 2019), it is also important to consider small group composition during integrated STEM lessons. While benefits of group work are well established (e.g. Baines et al., 2003; Fredricks et al., 2018; Fung et al., 2018), there are also well documented issues related to equity in small group participation (e.g., Jovanovic and King, 1998; Mewborn, 1999; Schnittka and Schnittka, 2016). Thus, the frequency of group work within STEM could promote inequitable participation and gender and racial stereotypes. One such strand of research has explored gender differences in participation in small group STEM activities through multimodal discourse analysis of video and transcripts of all boy, all girl, and mixed gender groups (Wieselmann et al., 2020a). This work suggests that boys and girls participate in different ways during small group STEM activities, with girls taking on more managerial roles (e.g., note-taking, keeping the group on task) and boys more inclined to participate when materials are physically manipulated (Wieselmann et al., 2019, 2020b). Interestingly, patterns of interactions shift as students transition from science-focused activities to engineering-focused activities (Wieselmann et al., 2019, 2020b). While girls did not appear to struggle in gaining access to or completing science tasks, they were more hesitant when faced with an open-ended engineering task that did not have a clear set of steps to follow to reach a pre-determined conclusion. Simultaneously, boys' participation in engineering increased when compared to the more-procedural science tasks, such that maintaining equitable participation became problematic within mixed-gendered groups. Assigned roles within these tasks that mirror cooperative learning rather than collaborative learning may be beneficial to minimize the challenges in navigating small group work in integrated STEM tasks (Dare and Roehrig, 2020). From these studies, it becomes clear that students need guidance with respect to working in small groups, which demands teacher effort to explicitly teach collaborative skills. Research has suggested that integrated STEM is a mechanism to promote interest in pursuing STEM careers and increase diversity within the field; however, this body of research suggests that the field should proceed with caution. More studies are needed to understand how the nature of the STEM tasks and the teachers' implementation of STEM curricula affect participation of groups underrepresented in STEM.

Future research in integrated STEM curriculum implementation

In order to continue to improve integrated STEM education, especially with respect to teachers' professional learning and curriculum implementation, more research needs to take place. Much of the research related to implementation relies on teacher self-report

data (e.g., Thibaut et al., 2018), and there is a need for more observational research. One of the limitations is the lack of an appropriate observation instrument that attends to the nuances of integrated STEM instruction and curriculum implementation. Existing instruments most commonly used by researchers, such as the Reformed Teaching Observation Protocol (RTOP) (Sawada et al., 2002), were designed prior to the development of the NGSS and were intended for use in reform-based science classrooms rather than integrated STEM learning environments. In order to facilitate the implementation of K-12 integrated STEM curricula and the development of the nascent integrated STEM education literature, new integrated STEM observation protocols are needed for use in K-12 science and engineering classrooms. Building on the experiences of *EngrTEAMS*, a new STEM Observation Protocol (STEM-OP) has been developed (Dare et al., 2021; Roehrig et al., 2019) which provides a common metric for future research related to the implementation of integrated STEM curricula in K-12 classrooms. With additional research on curriculum development and implementation, as well as teacher professional development opportunities, the field of STEM education can become better poised to meet the challenges of preparing all students to be proficient in STEM practices and habits of mind, regardless of whether they enter a STEM career.

Introduction

Play is a leading activity that is fundamental to a child's learning and development (Piaget, 1952; Vygotsky, 2016). Play naturally provides high motivational forces, a zone of proximal development, and social engagement (Vygotsky, 2016). Through play, children learn about the world around them and develop self-regulation, oral language, cognitive, and social competence skills (Coople and Bredekamp, 2009; Elkind, 2007; Piaget, 1952; Vygotsky, 2016).

Unfortunately, play has been rapidly disappearing from our children's lives (Brown and Vaughan, 2009; Gray, 2013; Hofferth and Sandberg, 2009; Louv, 2005; Miller and Almon, 2009). For example, a comparison study of how US children spent their time showed that children age six to eight spent 25% less time in indoor/outdoor play in 1997 than they did in 1981 (Hofferth and Sandberg, 2009). Among the many reported reasons for this decline of play were increase demands of academic standards in younger age (Bassok et al., 2016; Carlsson-Paige et al., 2015; Miller and Almon, 2009), and social pressure of extra-curriculum activities (Brown and Vaughan, 2009; Gray, 2013; Louv, 2005). While these and other factors push play out of the children's lives, at the same time more reports of declining physical and mental health of children, such as child's obesity, hyperactivity, and general anxiety, circulate through public media and academic communities (Burstein et al., 2019; Fryar et al., 2014). Recognizing play as a leading activity of learning and increased academic demands on children from a very young age has prompted educators and researchers to look for ways to integrate play within and across all learning environments (Zosh et al., 2018).

In addition to framing play as fundamental to children's development, science, technology, engineering, and mathematics (STEM) is an important component for education – economic and national security in terms of workforce development (Kuenzi, 2008; Jang, 2016; National Academy of Science [NAS], 2011), diversifying the field to a more diverse population (van den Hurk et al., 2019; Watson and Froyd, 2007), and development and use of STEM-literacy skills, practices, and knowledges by citizens (Bybee, 2010; Maass et al., 2019; McDonald, 2016; Zollman, 2012). However, research has shown how K-12 schools and universities are not preparing students to be agents of social change (Beckwith and Huang, 2005; Garibay, 2015), to develop the skills, knowledges, and work activities needed to enter the STEM workforce (Jang, 2016; Maass et al., 2019; Organization for Economic Cooperation and Development, 2016), or to view STEM as a meta-discipline as opposed to independent disciplines (Zollman, 2012). Changes to the STEM learning environment has been proposed as one factor as individuals are in a continuous dialog with their physical and socio-cultural environment (Eshach, 2007; Falk and Dierking, 2000). Specific changes include use of

authentic, student-generated, and/or interdisciplinary real-world problems, provide opportunities for students to apply previously learned skills and knowledge through multiple forms of representations, encourage collaboration, and teacher guidance (Glancy and Moore, 2013; Hatisaru et al., 2019; Struyf et al., 2019).

We argue that another approach to addressing how K-12 schools and universities are preparing students for global, national, and societal issues in STEM is through a play perspective. Conversely, we also contend that the STEM learning environment is a potential context for addressing the decline in play. Therefore, we conducted a literature review specific to play in STEM learning environments to address the following two research questions: (1) How is play conceptualized and operationalized in research within STEM learning environments? How might this differ by STEM field? (2) Utilizing play as a research lens, what characteristics of the STEM learning environment lead to positive developmental outcomes in children and young adolescents? The significance of this study is that it examined research literature across two fields, play research and STEM learning environments. This study also revealed gaps in the research literature related to play within the STEM learning environments including lack of research on the play for upper elementary and middle grades (9–14 years) and favoring math over other STEM fields. Additionally, this study highlighted the need for further research in embedding play within academic standards for all learners and exploring the social nature of play within the STEM learning environments.

Methods

Below we outline the process used to conduct the systematic literature review, which was informed by the PRISMA guidelines for systematic literature reviews (Moher et al., 2009). We also detail our analysis of the included articles to gain an understanding of play scholarship across formal, informal, and non-formal STEM learning environments.

Inclusion and exclusion criteria

Articles were initially screened based on their abstract and title, and their potential to meet the following inclusion criteria: (1) full-text empirical research utilizing methods and procedures of reporting standards for research studies as described by the American Psychological Association (APA) Publications and Communications Board Task Force (see Appelbaum et al., 2018; Levitt et al., 2018); (2) published between 1989–April 2020 in peer-reviewed journals, book articles, conference proposals, or conference proceedings; (3) published or translated into English; (4) included birth to 18 age group as a participant group or individual; (5) defined and/or situated within a theoretical or conceptual framework specific to play (e.g., Fleer, 2009; Vygotsky, 1978); and (6) conducted in a STEM learning environment defined as any physical space in which children and/or adolescents are provided with opportunities to engage with peers, adults (e.g., parents, educators), and objects/materials that promote an understanding of science, engineering, technology, and/or mathematics knowledges, literacies, and practices. This included objects and material that may not initially be viewed as related to STEM, but were transformed as such through children and/or adult's play (e.g., barrels of toy food, shopping baskets, and cash register used to engage in spontaneous numerical moments; Braham et al., 2018).

Search and data collection process

Articles were identified through the following databases: Academic Search Complete, Education Source, Environment Complete, ERIC, JSTOR, Library, Informational Science, & Technology, and PsychINFO. We used a combination of search terms, with the term “play” in the subject line being used in every search as to narrow and focus on the most relevant publications. This was used with a combination of search terms focused on the environment (i.e., learning environment, formal learning or non-formal learning or informal learning, out-of-school, summer programs, after school programs, library, museum, education environment) and STEM (e.g., STEM Education or science or technology or engineering or mathematics, science, technology, engineering, and mathematics). An asterisk was used to find relevant terms. For example, math* should capture similar terms such as maths and mathematics.

Based on the title and abstract, we maintained 87 full text articles to assess for eligibility based on the inclusion criteria. Next, we extracted the following information in the form of direct quotes: (a) research aim/questions, (b) how play was defined and situated in relevant literature, (c) context (e.g., preschool, playground), (d) STEM learning environment, and (e) results. Through this process, we discussed and removed 39 articles for four reasons: (1) did not clearly define play (e.g., Nel et al., 2017), (2) was not situated with a STEM learning environment (e.g., Hoskins and Smedley, 2019), (3) not in the targeted age group (e.g., Savin-Baden, 2010), and (4) not an empirical study (e.g., Castell et al., 2014). Forty-eight articles remained that fit our inclusion criteria. To ensure that we captured the relevant empirical research for this study, we used Web of Science to search for scholarship that cited the articles maintained (i.e., forward search) and fit our inclusion criteria. This yielded an additional 14 articles. Next, we conducted a backward search, which involved examining the references of the 48 articles for relevant articles. This produced an additional 14 articles. This process accumulated 76 articles, book articles, conferences, or proceedings to address the two research questions (see Fig. 1).

Fig. 1 Flow diagram illustrating the search process. Adapted from Moher et al. (2009).

Data analysis

Research question one

Play was operationalized according to how the play was initiated, who the play was directed by, and whether there was an explicit learning goal (Zosh et al., 2018). The context of the studies was denoted as free play, guided play, games, co-op play, playful instruction, direct instruction, or a combination of play. These were identified by each study's description of the activities located in the study's aims/purpose and/or methods section. Free play was characterized as an activity during which a child initiates and directs play without a pre-determined learning goal. To fully embrace the scope of the free play within the study, subcategories identifying the setting of the free play were considered (indoor, outdoor). Guided play was characterized as initiated and structured by an adult with an explicit learning goal in mind and directed by a child. Upon examination, two subcategories were added to further specify the characteristics of the guided play based on whether the initial input was an adult setting up the physical environment or whether the initial input was an adult inviting a child in social learning (Vygotsky, 1978). Game play was characterized as an activity that was adult-initiated and child-directed with an explicit learning goal using a game with rules. Two subcategories, didactical (i.e., non-technical) and virtual/digital were added to specify the setting of the play environment. Co-opted play was characterized as an activity that was initiated by a child and then directed by adults to achieve an explicit learning goal. Zosh et al. (2018) described the co-opted game as the adult intervening, redirecting, and changing the child's initial task to match the adult's learning goal. We extended the co-opted play characterization to include play initiated by a child during which an adult intervened by matching a specific learning goal to the child's original play. Playful instructions were characterized as adult initiated and directed with an explicit learning goal. Direct instructions were characterized as adult initiated and directed with an explicit learning goal. Articles that reported studies with exclusively direct instructions were not included in our study since they did not satisfy our inclusion criteria. However, there were several articles reporting comparison studies of free play, guided play and direct instructions (e.g., Bulunuz, 2013; Eason and Ramani, 2020). These are identified in our analysis as comparison.

Table 1 summarizes the types of play utilized to address the first research question, as well as the type of learning environment (i.e., formal, non-formal, or informal; Eshach, 2007) that was associated with each play type. Eshach's characterizations are not restricted to a physical space (e.g., all classrooms as formal environments), but how the learning environment is structured. Formal

Table 1 Types of play as associated with learning environments.

<i>Codes</i>	<i>Play definitions (Zosh et al., 2018)</i>	<i>Settings (Eshach, 2007)</i>	<i>Examples</i>
Free play	Child-initiated	Informal	Edens and Potter (2013)
• Indoor	Child-directed		Hallström et al. (2015)
• Outdoor	No explicit learning goal		Worthington and van Oers (2016)
Guided play	Adult-initiated	Formal	Adbo and Carulla (2019)
• Environment setup	Child-directed	Non-formal	Fleer (2020)
• Social learning setup	Explicit learning goal	Informal	Tian and Luo (2019)
Games play	Adult-initiated	Formal	Guberman et al. (1998)
• Didactical	Child-directed	Non-formal	Danby et al. (2018)
• Virtual/Digital	Explicit learning goal	Informal	
	Games with rules		
Co-opted play	Child-initiated	Informal	Hao and Fleer (2017)
	Adult-directed		Magnusson and Pramling (2018)
	Explicit learning goal		
Playful instruction	Adult-initiated	Informal	Watanabe (2017)
	Adult-directed		
	Explicit learning goal		
Direct instruction (non-play)	Adult-initiated	Formal	Fisher et al. (2013)
	Adult-directed		
	Explicit learning goal		

environments were characterized as structured, compulsory, teacher-led, potentially oppressive, and sequential. Non-formal environments were characterized as structured, voluntary, guided or teacher-led, usually supportive, and non-sequential. Informal environments were described as unstructured, voluntary, spontaneous, learner-led, and supportive. As an example, Bairaktarova et al. (2011) conducted a study in two mixed age preschools in a university-affiliated developmental center. This study was categorized as informal because the environment was created as free playtime - learner-centered, unstructured, and spontaneous (Eshach, 2007). As we coded the STEM environment for each study, we noticed how the learning environment was aligned with the play definitions by Zosh et al. (2018). This association is represented in Table 1.

Similar to Radovic et al. (2018), conceptualization of play was completed through highlighting central words and concepts from each article's definition of play. These central words and concepts were coded along three dimensions of play as play is a complex, in-flux activity (Hännikäinen and Munter, 2018; Reikerås, 2020). For the first dimension, we coded as to whether play was defined as a solitary activity or as a social activity in which play was done with others including peers, adults, and siblings. The second dimension we identified was concepts or practices/processes. Concepts were framed around play for cognitive development, such as scientific and mathematical concepts, while practices/processes were focused on ways of talking, acting, and behaving like an individual in a STEM field. The last dimension was coded along imaginary (e.g., role-play, hand is a telephone), manipulative (e.g., blocks, puzzles), learning (e.g., games), and creative (e.g., creating videos) (Bronson, 1995). To illustrate, we included a short excerpt from Schmitt et al. (2018, pp. 181–182) in which we italicized defining play features.

Block play in preschool provides a context where children can learn various skills (e.g., problem solving, perspective taking) through their interactions with both blocks and peers (Ginsburg, 2006). Engaging with blocks provides children with opportunities to reason and understand concepts of space and physical properties of objects (Verdine et al., 2017). Further, block play is social, verbal, and facilitates shared play, thereby giving children an opportunity to exchange ideas with peers and work together.

We coded the conceptualization of this study as social (e.g., “facilitates shared play”), manipulative (e.g., “physical properties of objects”), and practices/processes (e.g., “learn various skills (e.g., problem solving, perspective taking)”). These dimensional codes were not mutually exclusive as some studies may have been identified as imaginary and manipulative for example.

Lastly, the STEM field or learning environment was characterized as science, technology, engineering, and/or mathematics as identified in each study's aims/purpose. As an example, Wolfgang et al. (2001) was characterized as a mathematics learning environment because the researchers examined how block play performance among preschoolers was a predictor (or not) of later mathematics achievement.

Research question two

For the second research question, articles were grouped by type of play as researchers continue to consider the types of play experiences that best support young children development (e.g., Eason and Ramani, 2020; Ferrara et al., 2011). Next, positive development outcomes were synthesized across studies within a type of play while also considering components of the learning environment that researchers highlighted as shaping and impacting youths' and adolescents' positive development.

Limitations

Several limitations must be acknowledged as part of this systematic review of the literature on play-STEM learning environment. One, we do not claim to have included every empirical study that met the inclusion criteria. As such, we limited our search to the six databases listed above and searched for the term “play” within the subject line only. Yet, as argued by Doyle (2003), it may not be necessary to find every research study as the purpose of this literature review is interpretation as opposed to prediction. Two, the search terms and use of Booleans (i.e., and, or) potentially restricted the number of included studies. Three, we recognize the threat of publication bias in that scholarship with results that are unfavorable are not published (Petticrew et al., 2008). Similarly, the second research question is focused on positive developmental outcomes for children and young adolescents, which we acknowledge does provide a complete picture of characteristics of the STEM learning environment that may not be fruitful. There were only two studies included in this review that did not conclude some positive outcome specific to STEM (Edens and Potter, 2013; Hanline et al., 2010).

Results

The majority of included studies in this literature review (87%) included participants that were between the ages of birth to eight while the other 13% were with participants aged 9–14 years. Additionally, a little more than half of the studies (52.6%) focused on mathematics, 21.1% focused on science, 14.5% on technology, 10.5% on engineering, and 3.9% on STEM broadly. Additional information (e.g., context, age/grade of participants) regarding the included studies can be found online at https://orb.binghamton.edu/mathematics_fac/10.

Below, we first provide information related to how play was conceptualized and operationalized in research within STEM learning environments. Next, we synthesized positive developmental outcomes for child participants by play type, as well as consider the nature of the learning environment. In the results, not every included study was cited but accounted for within the synthesis of the findings. These studies are identified with an asterisk (*) in the reference section.

Research question one

Fig. 2 illustrates how play was conceptualized in research within STEM learning environments, as well as any differences that may exist by STEM field. The majority of research emphasized the social nature of play (e.g., Danby et al., 2018). Moreover, about two-thirds of the studies emphasized the application and understanding of STEM skills and concepts (e.g., Bulunuz, 2013; Worthington and van Oers, 2016). As an example, Gold et al. (2020) examined the association between engineering play with wooden blocks

Fig. 2 Alluvial representation of the three dimensions of conceptualizations of play by STEM field.

Fig. 3 Dimensions for conceptualizing play, concepts and/or practices/processes and play perspectives, by STEM field.

and 110 preschoolers' knowledge of numeracy and geometry, as well as the preschoolers' spatial skills. Additionally, with the exception of creative play, the majority of studies in this literature review are conceptualizing play as imaginative (e.g., Bird, 2020), manipulative (e.g., Tian and Luo, 2019), and learning (e.g., Bachman and Dierking, 2011).

Fig. 3 highlights any differences by STEM field based on two of the dimensions for conceptualizing play, concepts and/or practices/processes and play perspectives, respectively. Research specific to the fields of science and mathematics more often viewed play in terms of conceptual development (e.g., Solis et al., 2017; Wolfgang et al., 2001) while research situated in the technology field viewed play in terms of the development of children's ways of talking, acting, and behaving like a STEM individual (i.e., practices/processes) (e.g., Lawrence, 2018). With respect to the other dimension, research in mathematics and engineering learning environments more often conceptualized play as manipulative, objects and materials that can be physically explored and handled (e.g., Bairaktarova et al., 2011; Trawick-Smith et al., 2017). On the other hand, research in science and technology learning environments included a higher percentage of studies that conceptualized play as imaginative (Enyedy et al., 2012; Han et al., 2015).

Fig. 4 displays how play was operationalized in research within STEM learning environments. The most common type of play was guided play (47%), social (28%) and environmental (19%), respectively. Therefore, a little less than half of the studies in this literature review are environments in which play is initiated and structured by an adult, but directed by the child (e.g., Andree and Lager-Nyqvist, 2013; Hassinger-Das et al., 2020; Howe et al., 2016). Free play accounted for 25% of the

Fig. 4 Alluvial representation of types of play by STEM field. Percentages do not add up to 100% due to rounding to the nearest whole percentage.

studies (e.g., [Bagiati and Evangelou, 2016](#); [Reikerås, 2020](#)) and game play accounted for 13% (e.g., [Siyahhan et al., 2010](#); [Stebler et al., 2013](#)). In addition, there are a few things to note about types of play by STEM discipline. One, in considering the spread of articles in the science field, there is a higher concentrate that operationalize play through a guided play – social lens (e.g., [Carulla and Abdo, 2019](#)). Two, the field of mathematics is the only discipline that has researched play through games that do not include a technology component (i.e., didactical), but were more often board games (e.g., [Guberman et al., 1998](#)) and/or card games ([Vogt et al., 2018](#)).

Research question two

Free play

In free play STEM environments, children are unrestricted to explore the objects within their environment (e.g., blocks, mirror, plastic food) and engage in play either independently or with others such as their peers. Research characterized as free play has shown several positive outcomes. One, children experienced and began developing STEM related concepts such as numeracy (e.g., [Emfinger, 2009](#)), geometrical shapes (e.g., [Gejard and Melander, 2018](#)), spatial transformations (e.g., [Levine et al., 2012](#)), measurement concepts such as money and time (e.g., [Worthington and van Oers, 2016](#)), and physical concepts such as magnetism (e.g., [Solis et al., 2017](#)). Two, there is a positive and significant correlation between early block play, as well as LEGO play, and children's mathematical achievement at the middle and high school levels ([Wolfgang et al., 2001, 2003](#)). Three, free play afforded children the opportunity to explore physical and digital objects and make connections to their everyday experiences (e.g., [Worthington and van Oers, 2016](#)), as well as transform these objects to be closer to their own interests (e.g., [Kjällander and Moinian, 2014](#)). Lastly, children engaged in practices common to engineers and mathematicians such as problem solving, innovation, argumentation, and goal setting (e.g., [Bairaktarova et al., 2011](#); [Sumpter and Hedefalk, 2015](#)).

Beyond access to physical and digital material in the environment, researchers examined other components of a learning environment that had a positive outcome for children engaged in free play. In general, researchers noted a positive shift when children collaborated with one another (e.g., [Trawick-Smith et al., 2017](#); [Reikerås, 2020](#)), as well as when children were engaged in independent play ([Reikerås, 2020](#)). Additionally, [Gold et al. \(2015\)](#) found that different free play environments elicited differences in the ways that children participated as engineers. For example, children were found to use more technical language per hour in the dramatic play area than in a traditional playground or Imagination Playground™ environment.

However, some researchers that examined the impact of free play concluded that teachers are a vital part of the learning environment as they are able to bridge or connect children's play experiences and development to scientific ([Fleer, 2009](#)) and mathematical concepts ([Trawick-Smith et al., 2016](#)). Time engaged in play, or even the number of structures built, does not necessarily have an impact on children's cognitive development ([Trawick-Smith et al., 2016](#)) as other researchers have found (e.g., [Levine et al., 2012](#)). These conclusions highlight a tension in the educational field ([Hedges, 2014](#)).

Guided play

Guided play studies (adult-initiated and child-directed) in which changes were made to the physical environment were done so in four ways – signage or caregiver prompt cards (e.g., [Hassinger-Das et al., 2018](#)), access to and structure around materials, objects and models (e.g., [Simoncini et al., 2020](#)), stations or exhibits (e.g., [Reinking et al., 2017](#)), and less whole-group teacher instruction ([Andrée and Lager-Nyqvist, 2013](#)). The studies that provided signage and/or caregiver prompt cards, as well as stations or exhibits, was to increase caregiver-child STEM-related interactions in everyday contexts such as supermarkets, bus stops, playgrounds, and museums, and to indirectly impact child outcomes (e.g., [Hassinger-Das et al., 2018](#); [Reinking et al., 2017](#)). Researchers concluded that providing such support and opportunities for caregivers led to positive impact on children's spontaneous focus on number ([Braham et al., 2018](#)) and some math language (e.g., fractions, measurement, whole numbers, spatial; [Hassinger-Das et al., 2018, 2020](#)). Studies in which novel materials, objects and models were provided and supported through prompts (e.g., include a ramp in your design; [Schmitt et al., 2018](#)) and educator provisions (e.g., [Bird, 2020](#)), positive child outcomes included shape recognition ([Schmitt et al., 2018](#)), early arithmetic strategies ([Simoncini et al., 2020](#)), and an understanding of how materials function within a meaningful and personal context ([Parekh and Gee, 2018](#)). Lastly, the study conducted by [Andrée and Lager-Nyqvist \(2013\)](#) argued that when teacher instruction mirrors a more inquiry-based approach, students are able to make sense of science concepts – the variety of nutrients that humans need – through spontaneous play that some may view as off-task behavior.

Studies in which adults created and provided social support within the STEM learning environment were more often planned and embedded play-based learning activities in non-formal (e.g., [Leung et al., 2020](#)) and formal learning environments (e.g., [Enyedy et al., 2012](#); [Sliogeris and Almeida, 2019](#)), including formal environments that create out-of-school contexts (e.g., bakery; [Edo et al., 2009](#)) as opposed to more natural and everyday interactions and experiences with family members (e.g., [Sikder and Fler, 2015](#)) and peers ([Ramani et al., 2014](#)). For example, three preschool educators in a study by [Gomes and Fler \(2019\)](#) planned and implemented play-based activities around Jack and the Beanstalk. These activities were embedded in children's regular activities and routines, and educators engaged and guided children in science concepts such as sound, vibration, and growth of plants through imaginary play. Findings from these studies concluded that children developed an understanding of STEM concepts such as complex numbers, operations and arithmetical situations ([Edo et al., 2009](#)), force and motion concepts ([Enyedy et al., 2012](#)), atoms and molecules ([Carulla and Adbo, 2019](#)), and the relationship between animals, their habitats and needs ([Sliogeris and Almeida, 2019](#)). Additionally, children engaged in age-appropriate practices similar to scientists, engineers, and technologists/artists (e.g., [Fler, 2020](#); [Leung et al., 2020](#); [Simpson et al., 2020](#)). For example, [Adbo and Carulla \(2020\)](#) described how children became familiar with how to use scientific tools such as magnifying glasses and microscopes.

As such, supporting young children's development within institutional practices and expectations can be challenging for teachers as play is not viewed as a legitimate way to meet learning expectations (e.g., [Andree and Lager-Nyqvist, 2013](#); [Sliogeris and Almeida, 2019](#)). So, what did the researchers in this literature review highlight as effective pedagogical strategies for play-based (or guided-play) instruction in STEM learning environments? These instructional moves are conscious and intentional; they see opportunities during play and make use of them in an appropriate way (e.g., [Carulla and Adbo, 2019](#); [van Oers, 1996](#)). One, educators posed questions that encouraged young children to describe their observations, make connections to STEM concepts, and test their certainty about assertions and solutions (e.g., [Adbo and Carulla, 2019](#); [DeLiema et al., 2019](#); [van Oers, 1996](#)). Two, educators utilized young children's everyday experiences and concepts within play to bridge connections to STEM concepts (e.g., [Gomes and Fler, 2019](#); [Sliogeris and Almeida, 2019](#)). [Adbo and Carulla \(2020\)](#) referred to this as sustained shared thinking, which implies the social nature of the interaction between teachers and children. Three, educators introduced and used mental and physical models and tools to conceptually orient children's play (e.g., [Carulla and Adbo, 2019](#); [DeLiema et al., 2019](#)). Additional strategies included wondering discourse, creation of imaginary situations ([Fler, 2019](#)), and use of gestures to support toddlers ([Lee et al., 2015](#)).

Game play

Game play, regardless if virtual or didactic, seemed to initiate and engage children in spontaneous mathematical (e.g., comparison of different objects; [Avraamidou et al., 2012](#)) and scientific understandings (e.g., how particles move based on its form; [DeLiema et al., 2019](#)). For example, 6-year old children engaged in an adapted game called Shut the Box (i.e., sum of two dice to shut a wooden tile) and were observed using and expanding upon a variety of counting strategies (or none at all) based on their individual competency levels ([Stebler et al., 2013](#)). Children were also observed engaging in problem solving strategies ([Guberman et al., 1998](#)). These spontaneous moments were not only a function of the game's rules and artifacts, but also supported through interactions with other such as their peers (e.g., [Danby et al., 2018](#)) and parents ([Siyahhan et al., 2010](#)). As expressed by [Danby et al. \(2018\)](#), collaboration and social interactions between novice and expert children were necessary for the novice to gain access to and be successful within the game play virtual environment. Providing such play-based games may also have more of an influence on children's positive dispositions as they expressed a sense of enjoyment and fun, described as less school like ([Vogt et al., 2018](#)).

Other play types

In looking across play types that were less common, the research continued to highlight children's positive development. For example, the two studies that operationalized play as playful instruction observed an increase in a child's mathematical ability (e.g., conservation concepts of numbers, liquids, and lengths; [Watanabe, 2017](#)) when the adult, in this case a parent, initiated

and directed a math quiz game and Piaget tasks during conversations and play in home environments (Watanabe, 2017, 2019). The co-opted STEM play environments illustrated how adults engaged in joint creation and elaboration of a child's imagined or fantasy world(s) grounded in STEM topics may lead to an understanding of how numbers are sequenced and how they can be combined (Magnusson and Pramling, 2018) or learning about Earth and space (Hao and Fleer, 2017). As such, the adult supports the child's experience within their playful exploration and as-if world through becoming a part of that world as opposed to situating the child's interest and engagement in STEM through transitioning from an imaginary play environment to reality.

Lastly, the comparison studies showed differing results in terms of which play environment was more beneficial for children's cognitive development. Eason and Ramani (2020) found that parents and children in a didactic learning environment engaged in more math talk with one another than parents and children in a comparable guided play learning environment. However, parents in both the formal and guided environments posed about the same amount of questions that encouraged their child to explain their thinking (e.g., "why"). Parents and children in the free or unguided play environment was found to use the least amount of math talk. Conversely, Ferrera et al. (2011) noted how the guided play environment with blocks elicited more spatial language from parents and children than parents and children in the preassembled block or formal play environment. Both of these environments were found superior to the amount of spatial language spoken by parents and children in the free block play environment. Moreover, Ferrera et al. (2011) also noted that these three play contexts – free, guided, and preassembled – elicited more spatial language than other play contexts that do not involve construction.

Fisher et al. (2013) and Bulunz (2013) also found favor with guided play environments than didactic or formal environments, as well as free play environments. For example, children in guided play demonstrated a stronger conceptual understanding of shapes (Fisher et al., 2013) and science concepts (e.g., make predictions and explanations, build cause and effect relationships; Bulunz, 2013) than children in comparable play environments. These results raise the question, what is it about the free play experience that did not lead to more math talk or a stronger conceptual base than guided play or didactic instruction? As expressed, free play environments do not necessarily provide children with the supports to notice particular features or objects as they are irrelevant to the children's play context (e.g., Ferrera et al., 2011; Fisher et al., 2013).

Discussion

Descriptives from the included studies situate the majority of research on play in STEM learning environments within early childhood contexts (i.e., birth to age 8) across a variety of settings such as school, home, playgrounds, and museums. This raises the question, Why? Why is this case when the research included here showed positive outcomes in terms of children's STEM development? Why is this case when research has indicated a decline in factors that strongly influence persistence in STEM (e.g., interest; Maltese and Tai, 2011) around middle grades (ages 11–14) (Osborne et al., 2003)? We argue that additional research should consider the characteristics of the STEM play learning environment that is most conducive to learning and development for learners of all ages. How might play be conceptualized and operationalized similarly and/or differently from that in early childhood settings? As noted by Leontev (1981) play is intrinsically motivating and unique in that the motive of play "does not lie in its result but in the content of the action itself" (p. 368); thus, emphasizing the process rather than the product. Additionally, the majority of scholarship included in this literature review was in the field of mathematics and less often in engineering and technology. With the increase in the use of technology (e.g., robotics, coding apps, and virtual reality) and engineering education across PK-12, there is an opportunity to further our understanding of play within STEM fields. We also argue a need for research on play across the STEM fields as K-12 and postsecondary learners are not being prepared to enter the STEM workforce viewing STEM as a meta-discipline (Zollman, 2012).

Research question one

In looking across the STEM play learning environment scholarship in this literature review, the majority conceptualized play as a social as opposed to a solitary endeavor, which support young children as social actors with social competencies (Engdahl, 2011) and the development of communication and collaboration skills vital to the STEM workforce (e.g., Jang, 2016). Additionally, the studies rarely viewed play as creative, but more often as imaginary, manipulative, and learning. We argue a need for research utilizing creative play within STEM learning environments as thinking creatively while solving ill-defined problems, as well as an esthetic or artistic sensibility, is considered an important work activity for individuals who work in STEM disciplines (Jang, 2016; Root-Berstein, 2015). There were also differences in terms of STEM fields as mathematics and engineering were more likely to conceptualize play through use of manipulatives (e.g., blocks, puzzles) while technology were more likely to conceptualize play as imaginary (e.g., creating fantasy worlds). Research grounded in science and mathematics also emphasized conceptual development more often than the development of practices and process. We hypothesize that this may be due to the emphasis of these two subject areas in formal schooling contexts and teacher preparation programs, as well as the number of standardized tests as markers of "success" in mathematics and science fields (see Chandler et al., 2011 and Roehrig et al., 2012 for a similar argument).

Research question two

As a body of scholarship, the included studies in this literature highlight the value of all types of play for young children and adolescents' development within STEM across a range of learning environments. Children were provided opportunities to develop an understanding of a range of science and math concepts (e.g., DeLiema et al., 2019; Enyedy et al., 2012; Fisher et al., 2013; Gejard and Melander, 2018), use mathematical language (e.g., Ferrera et al., 2011; Hassinger-Das et al., 2020), and engage in practices common to STEM professionals (e.g., Simpson et al., 2020; Sumpter and Hedefalk, 2015). Thus, why do we see a decrease in play occurring both in and outside what can be considered schooling hours (e.g., Hofferth and Sandberg, 2009)? Why do we see a decrease in play when there is potential for long-term STEM impacts (Wolfgang et al., 2001, 2003)? How do we embed play within the demands of the academic standards for all learners and not only learners in early childhood settings? The findings from this analysis provides some insights into this question.

Across the play types, there are at least two commonalities that we can utilize when developing play in STEM learning environments for all learners. One is access to objects and materials for their own right (e.g., blocks, microscopes) and for their potential to transform reality into an imaginary situation (e.g., plastic banana becomes a phone; Bird, 2020). We highlight access as Simoncini et al. (2020) described how access to resources such as Duplo Lego is a barrier in some countries. But we also see potential in transforming household objects and recyclable materials (e.g., cardboard box), as well as items in nature (e.g., tree branch), into opportunities for play with STEM learning environments (e.g., Parekh and Gee, 2018). Two is the connection to learners' everyday experiences, everyday experiences that lead to the development of STEM concepts (e.g., Hao and Fleer, 2017; Vogel, 2013). However, as argued by some, the teacher is a vital part of making these connections between children's everyday experiences and understanding of concepts (e.g., Gomes and Fleer, 2019; Sliogeris and Almeida, 2019). An approach to this may be grounded in the funds of knowledge framework, a framework for conceptualizing students' homes, cultural, and everyday experiences as sources of knowledge to use in the learning environment (González et al., 2005). Utilization of this knowledge creates a "third space" or an "integration of knowledges and Discourses drawn from different spaces ... that merges the "first space" of people's home, community, and peer networks with the "second space" of the Discourses they encounter in more formalized institutions such as work, school, or church" (Moje et al., 2004, p. 41). We contend that this extends to STEM learning environments whether non-formal, informal, or formal setting and with caregivers as they have a foundational knowledge of their child's everyday experiences and have the ability to build upon and make connections between these experiences and STEM concepts, practices and processes within play.

As alluded to above, the social nature of play is an important component of the STEM learning environment, but there seems to be a difference in outcomes based on the role and interaction with others – educators, caregivers, siblings, and/or peers. The comparative studies included in this literature review highlight this as the majority confirmed that guided play (adult-initiated, child-directed) led to more mathematical language from parents and children, for example, than mathematical language from parents and children in formal play and free play STEM learning environments (Ferrera et al., 2011). It is argued that free play environments do not afford children with the necessary supports to make connections to STEM concepts, practices and processes (e.g., Fisher et al., 2013). We also see this argument by others scholars such as Fleer (2009), Trawick-Smith et al. (2016), van Oers (1996), Bulunz (2013), and Abdo and Carulla (2020) to name a few. We argue that additional research be conducted that compares developmental outcomes within different STEM play learning environments, including co-opted play environments as the two studies in this literature review illustrated how the adult entered the child's playful world to co-create mathematical and scientific concepts specific to the child's interest (Hao and Fleer, 2017; Magnusson and Pramling, 2018). Additionally, as these studies argued, the instructional practices here are conscious and intentional (e.g., van Oers, 1996) as there is a fine line between supporting the child's play and directing the child's play to an experience that does not resemble play. Simpson et al. (2020) referred to this as missed opportunities, opportunities to engage children in further play around STEM concepts, practices and processes mirror that of instruction and not that of play.

Conclusion

The goal of this systematic literature review was to examine play in STEM learning environments as a means to consider play as a potential for addressing global, national, and societal issues in STEM (e.g., Kuenzi, 2008; van den Hurk et al., 2019) and conversely, how STEM learning environments can be framed as a context for human (not only child) development through play (e.g., Bassok et al., 2016; Coople and Bredekamp, 2009). The positive children and adolescent outcomes outlined in this study support the notion of play in STEM learning environments as establishing the seeds or foundation to address concerns around economic and national security, a diverse STEM workforce, and a STEM-literate society; yet, our understanding does not extend beyond the few studies that included a population beyond the age of 14. Reframing STEM research through a play lens with a wider age range of learners may shed more light on this, including individuals in the STEM workforce and their opportunities to "play" with ideas and objects. This literature review also highlighted how STEM play learning environments can be utilized to alleviate some of the anxiety and pressures around achievement and academic standards of educators and caregivers (Bassok et al., 2016; Miller and Almon, 2009) as young children and adolescents were gaining an understanding of STEM concepts, practices and processes through play.

Introduction

STEM is ubiquitous. Toys, coloring books, and magazines for children. After school programs, summer camps, and podcasts. Teachers and professional development programs. Courses, internships, and schools. International journals, special issues, and conferences. Occasionally there is a merging of the arts and design (STEAM or STEM-D), reading or religion (STREAM), or medicine (STEMM). Nevertheless, STEM has remained most popular and become a favored marketing maneuver for products, events, practices, programs, and policies.

Indeed, STEM has proliferated in popularity and become a natural part of the vernacular since the acronym was coined at the National Science Foundation (NSF) in the 1990s as a way to group science, technology, engineering, and mathematics (Bybee, 2013). Yet, the meaning of the term, STEM, remains an enigma and varies based on individual interpretation; from teachers to administrators, policymakers, and the general public, a universally accepted definition does not exist. However, an integrated definition of STEM, in which two or more STEM domains are “bound by STEM practices within an authentic context for the purpose of connecting these subjects to enhance student learning” (Kelley and Knowles, 2016, p. 3), has been more widely embraced (Koehler et al., 2015; Vaval et al., 2019).

This integrative nature of STEM is recognized by the *Next Generation Science Standards* (NGSS), from unifying crosscutting concepts to math and literacy connections:

What is different in Next Generation Science Standards (NGSS) is a commitment to fully integrate engineering design, technology, and mathematics into the structure of science education by raising engineering design to the same level as scientific inquiry when teaching science disciplines at all levels from kindergarten to grade 12. This new integrated approach to science education is sometimes referred to by the acronym STEM.

NGSS Lead States (2013).

In effect, STEM is a recognition that the disciplines are not siloed. Everyday challenges are “multidisciplinary, and many require integration of multiple STEM concepts to solve them” (Roehrig et al., 2012, p. 31).

Before a thorough consideration of what STEM is and should be, particularly in practice, there has been an international race to jump on the STEM bandwagon (Lesseig et al., 2017). The rationale is that STEM propels innovation, economic growth, and a nation’s standing and prestige (Sahin et al., 2015). It is in this context that STEM schools have been established, which is the focus of this entry. First, I contextualize the propagation of STEM schools by exploring the rise of STEM. What follows is an overview of the varieties of STEM schools and models, along with their common characteristics. I then offer an overview of the extant empirical

literature on STEM schools before closing with recommendations for future research endeavors and thoughts on the way forward, with equity considerations in mind.

Rationale for the rise of STEM education

Rallying cries for STEM education are not new. In fact, much of the STEM hype can be traced back to the late 1950s when the Soviet Union launched the satellite, Sputnik 1, on October 4, 1957 (Bybee, 2013). This event sparked a fundamental reckoning about the United States' global competitiveness. In particular, Sputnik stimulated societal calls and support for major science and mathematics curriculum reform projects funded by the National Science Foundation (NSF), such as the Biological Sciences Curriculum Study (BSCS) and the School Mathematics Study Group (MSG), that spanned decades afterward (Koehler et al., 2015). Without accompanying, ongoing professional development to support teachers with a new paradigm of inquiry-based teaching, these changes did not make a widespread dent in the fabric of daily classroom life; teachers relapsed into teaching the way they had taught previously, which was at odds with reform-based teaching and learning.

In 1983, *A Nation at Risk* was released, which painted a grave portrait of the United States' education system (NCEE, 1983). This report stated that U.S. students were falling markedly behind their counterparts in other developed nations and that students had abysmal deficits in basic academic skills and knowledge, let alone critical thinking. Frameworks and learning standards followed, such as *Project 2061: Science for All Americans* (AAAS, 1989), *Benchmarks for Science Literacy* (AAAS, 1993), and the *National Science Education Standards* (NRC, 1996). These documents communicated the importance of scientific literacy for all Americans, not just those deemed gifted and talented as had been the case in the 1960s (Bybee, 2013). Furthermore, *Rising Above the Gathering Storm* (NAS, 2007) was another report that issued a clarion call for the U.S. to revive its global status through major overhauls in STEM education. Some of the recommendations included vast improvements to K-12 science and mathematics education, an intensified approach to research and innovation, and the creation of high-paying jobs, accompanied by innovation, manufacturing, and marketing enhancements.

Indeed, countries the world over have substantially invested in such plans to cultivate STEM professionals capable of addressing complex, global challenges. These initiatives have been interpreted as critical infrastructure for bolstering a nation's well-being and include STEM education, teacher preparation, and professional development programs (Sharma and Yarlagaadda, 2018). For example, researchers of STEM education in the African countries of Liberia and Ethiopia have embraced STEM training to guard against the next pandemic and tackle road and housing construction concerns (Tardy Hackman et al., 2021; Melak and Singh, 2021). Similarly, others have acknowledged localized challenges in Vietnam due to climate change—including rising sea levels, increased flooding, landslides, and droughts—that could be further understood and addressed with integrated STEM expertise (Nguyen et al., 2020). China, India, Japan, The Philippines, Qatar, Singapore, South Korea, Thailand, Turkey, and Vietnam are countries in Asia documented in the literature with increased STEM interest and engagement (Ali et al., 2021; Changtong et al., 2020; Choi, 2014; Kurt and Benzer, 2020; Nguyen et al., 2020; Sharma and Yarlagaadda, 2018; Teo and Osborne, 2014).

Central and South American countries pursuing STEM include Ecuador and Chile (Bascope and Reiss, 2021; Ching-Chiang and Fernández-Cárdenas, 2020). In particular, Bascope and Reiss (2021) have advocated for sustainable STEM education in Chile that supports "habits of using scientific evidence to justify sustainable practices" and "the value of STEM education for society as a whole" (p. 2). Australia and New Zealand have invested heavily in training math and science teachers (Gough, 2021). Germany, Serbia, Spain, Sweden, and the United Kingdom are European countries that have been documented with increased support in STEM education as well (Andrée and Hansson, 2013; Hernández-Serrano and Muñoz-Rodríguez, 2020; Maksimović et al., 2020; Moote et al., 2020; Stoeger et al., 2021).

Undoubtedly, countries around the world are participating in this development of STEM infrastructure. At the same time, there is growing recognition that "STEM education should be inclusive and available to every student" (Nguyen et al., 2020, p. 12), given enduring gender gaps in physics, engineering, and computer science, which have continued to be male-dominated (Gough, 2021; Stoeger et al., 2021). Discrepancies in STEM education access and opportunities for ethnic minorities and individuals in rural areas are also worldwide injustices (Wang and Yang, 2021; Tardy Hackman et al., 2021; Melak and Singh, 2021). As Nguyen et al. (2020) put it, in the context of Vietnam, STEM is still largely often only for the elite given that "STEM education has become commercialised and dominated by private high-tech companies and schools in the large cities" (p. 12). Thus, STEM education has the potential to close opportunity gaps as well as exacerbate them.

Varieties of STEM schools

STEM schools are a manifestation of these global calls for STEM education and have recently carved out a unique area of educational research. While Teo and Osborne (2014) noted that STEM schools exist in the Philippines, Singapore, South Korea, and Australia, these schools have not been examined in the empirical research base. To date, the research literature has only examined STEM schools in the United States, and as such, this entry will focus on STEM schools in this context. In this section, I will provide an overview of the varieties of STEM schools, outlined in Fig. 1.

Fig. 1 Varieties of STEM schools.

Selective STEM schools

Specialized STEM schools are not new; they have been around since the turn of the 20th century, although their name has changed over time. Initially referred to as “manual training schools,” they became specialized science, mathematics, and technology (SMT) schools, and most recently have been referred to as “selective” STEM schools (Erdogan and Stuessy, 2015). In fact, Stuyvesant High School in New York City, which opened in 1904, is considered the first selective science and math high school in the U.S., originally only admitting boys. Others such as Brooklyn Technical High School and Bronx High School of Science in New York City opened in 1922 and 1938, respectively, with the goal of preparing students to attend college or begin technical careers. Like Stuyvesant High School, initially only male students were admitted.

Targeting the development of gifted scientific researchers and engineers, the National Defense Education Act spawned the creation of more specialized science high schools in 1964 (Subotnik et al., 2019). These STEM schools are known as selective STEM schools because they have been discerning in their entrance requirements and therefore admit only a select few students. They have narrow admissions requirements, often based on prior academic achievement and entrance exams; in some cases, they also require financial means to attend (Johnson and Sondergeld, 2020). Selective STEM schools have been lauded as “incubators for talent development” (Subotnik et al., 2016, p. 236), and the National Consortium for Specialized Secondary Schools of Mathematics, Science, and Technology (NCSSSMST), founded in 1988, has also played a significant role in the advancement of these schools (Erdogan and Stuessy, 2015).

Yet, selective STEM schools tend to serve students from traditionally privileged backgrounds and are less diverse. For example, in the Almarode et al. (2016) study, which explored the educational and career outcomes of selective STEM high schools, 70.1% of participants were Caucasian, 78.8% had English as their primary language, 81.2% had a parent/guardian with postsecondary education, and 56.7% had a parent/guardian in a STEM-related career. Additionally, with entrance exam performance as the sole criterion for admissions in a selective New York City STEM high school, only 4% of the student population was Black and Hispanic (Pride, 2014). In essence, selective STEM schools often lack racial/ethnic and economic diversity and tend to serve students from privileged backgrounds, typically overrepresented in STEM. As such, they operate with a tacit view that talent and giftedness are innate and that STEM education should be reserved for a small group of individuals.

Inclusive STEM schools

In contrast, more recent STEM education initiatives and trends aligned with education reform documents have sought to address disproportionate STEM participation through more intentional efforts at ensuring STEM access and opportunities for minoritized students (Johnson and Sondergeld, 2020). As Vaval et al. (2019) put it, the goal has been to “increase the number of students pursuing advanced degrees and careers in STEM, STEM literacy for all students, and the participation of women and minorities in the STEM workforce” (p. 1153). That is, while the STEM movement in the 1960s was primarily concerned with high-performing students and creating career scientists and mathematicians, today’s movement is more inclusive, centering STEM literacy for all students, regardless of their career intentions. All individuals should be able to acquire STEM knowledge and apply it, recognize how STEM disciplines shape society and vice versa, understand STEM disciplines as human endeavors, and engage in critical issues as concerned, informed individuals (Bybee, 2007).

It is with this inclusive mindset that in 2010, under former President Barack Obama, a report from the President’s Council of Advisors on Science and Technology (PCAST) clamored for the recruitment and training of 100,000 new STEM teachers with deep content knowledge and pedagogical expertise to effectively inspire and educate the nation’s youth. The report also called for the creation of at least 200 new STEM-focused high schools and 800 STEM-focused elementary and middle schools within the next decade. Further, the report stated that many of these schools should serve “minority and high-poverty communities”

and “take steps to ensure that all schools and school systems have access to relevant STEM-expertise” (PCAST, 2010, p. 8). STEM schools were lauded as unique national resources and laboratories for innovative STEM education approaches.

Since the PCAST report, the number of inclusive STEM-focused schools has increased in the United States (Johnson and Sondergeld, 2020). Rogers-Chapman (2014) had a list of 221 inclusive STEM high schools in the U.S., up from 100 in 2008 as documented in the Means et al. (2008) study. Statewide initiatives in North Carolina, Ohio, and Texas also catalyzed the creation of more ISHSs. In fact, the first inclusive STEM schools in Texas, known as T-STEM schools, were funded in 2006. A funding stipulation required that schools could not select students based on prior academic performance and had to have a student population that was more than 50% economically disadvantaged or more than 50% from racially/ethnically minoritized groups. From 2009–2010, Texas invested approximately \$120 million in 51 academies and 7 T-STEM technical assistance centers, a majority of which were established in major metropolitan contexts (Young et al., 2016).

Unlike selective STEM schools, inclusive STEM schools admit students who wish to attend based on interest, without exclusive measures of aptitude and prior achievement. As such, inclusive STEM schools actively recruit students interested in STEM who are traditionally underrepresented based on race/ethnicity, family income, and gender. Inclusive STEM schools consider “instructional and cultural supports to meet students where they are, providing relevance to their background, life experiences, and cultural values/norms to facilitate learning” (Johnson and Sondergeld, 2020, p. 2). Inclusive STEM schools are built on the idea that talent resides within every child and that STEM competencies can be developed and cultivated with appropriate access, opportunities, and scaffolds.

STEM Career and Technical Education (CTE) schools

A third broad category of STEM schools include STEM-focused Career and Technical Education (CTE) schools, often located in educational centers, comprehensive high schools, or career academies (NRC, 2011). STEM CTE schools aim to prepare students for college with a primary focus on practical, real-world applications through STEM-related career preparation, such as health services and information technology (Erdogan and Stuessy, 2015; Vaval et al., 2019). These schools have a broader purpose of preventing students from dropping out of school. In particular, students with learning disabilities are traditionally underrepresented in high school STEM courses, as they accrue fewer STEM courses in high school and graduate college less ready in STEM areas than students without learning disabilities (Freeman et al., 2021). The recent reauthorizations of the Carl D. Perkins Career and Technical Education Act in 2006 and 2018 called for increased access to a CTE curriculum as well as increased STEM supports for students with disabilities. As a result, there has been a greater focus on applied STEM CTE coursework—such as engineering technology and information technology—that center on application of science and math concepts for real-world STEM tasks (Plasman and Gottfried, 2018). Applied STEM coursework is one potential path by which STEM material can become more accessible for students (Freeman et al., 2021).

STEM school models

Regardless of category, STEM schools come in a variety of models including residential, comprehensive or self-contained, schools-within-schools, half-day or part-time, and early college (Almarode et al., 2016). In residential STEM schools, students live and study in a school environment that focuses on STEM learning. Residential STEM schools tend to serve students from across a state. Comprehensive or self-contained schools are similar to traditional high schools; they are independently administered and fully functional, stand-alone schools, with a concentrated focus on advanced STEM topics.

In the school-within-a-school model, independent STEM programs exist within larger, comprehensive schools (Tofel-Grehl and Callahan, 2014). Students can study in specific STEM classes while still being members of the broader school community and also participate in classes with peers outside of the specialized school curriculum. Likewise, students not enrolled in the STEM program can take advanced courses in the program.

In half-day or part-time programs, students enroll in advanced STEM courses outside of their home school but attend non-STEM classes with peers in their home school. While the comprehensive and school-within-a-school programs tend to be located in major urban areas, the half-day or part-time programs often operate in poorly resourced, rural counties that serve entire geographical regions. Students are bused to the school for part of the day from a number of secondary schools to participate in science-related disciplines for a portion of the day, while the rest of the day is spent at their home high school. Sometimes these programs occur at local colleges and universities. Early college STEM programs allow students to skip the last 2 years of high school and enroll in a local college early (Almarode et al., 2016). Due to partnerships between a high school and local college or university, students in early college programs can graduate from high school with a diploma and up to 2 years of college credit or an associate’s degree in a STEM-related field (Tofel-Grehl and Callahan, 2014).

Overall, STEM schools exist in a variety of geographical contexts. Although most are located in large metropolitan areas, there are STEM schools that serve rural populations. STEM schools can be private or public, including charter and magnet schools (Kloser et al., 2018; Judson, 2014; Means et al., 2008), and exist at elementary, middle, and high school levels. STEM schools tend to be small schools of choice with a STEM-related focus or theme such as health sciences or engineering and technology (Edmunds et al., 2017).

Characteristics of STEM schools

As evident from the previous section, no single model for STEM schools exists. However, STEM schools share a number of characteristics, or critical components, including a mission to prepare students for STEM pathways. A focus on one or more STEM disciplines, well-trained teachers, advanced coursework, innovative technology, and partnerships with community members for authentic research experiences, mentorships, and internships are others (Subotnik et al., 2016). While inclusive and selective STEM schools both share these features, selective STEM schools do not share an inclusive vision of actively recruiting and selecting students from underrepresented backgrounds without record of achievement based on traditional measures.

A body of research details critical components of inclusive STEM-focused high schools (ISHSs) based on literature reviews (Peters-Burton et al., 2014a) as well as document analyses according to school websites and national statistics databases, standardized test scores, interviews, and other publicly available data (LaForce et al., 2016; Scott, 2012). Scott (2012) noted that ISHSs have rigorous course requirements with electives centered on STEM content and real-world problem-solving applications, internships, and capstone projects. From an examination of 20 ISHSs across the U.S., LaForce et al. (2016) identified eight essential elements: personalization of learning; problem-based learning; rigorous learning; career, technology, and life skills; school community and belonging; external community; staff foundations; and external factors. Another study explored the cultural dimensions that influence curriculum and instruction for inclusive STEM schools at elementary, middle, and high school levels (Lesseig et al., 2018). Unique student learning cultural dimensions across the grade levels include the school's vision, community partnerships, course scheduling, and testing pressures along with instructional practices, interdisciplinary collaboration, and teacher content knowledge.

Perhaps most encompassing of ISHS critical components is the work of Peters-Burton et al. (2014a) and Lynch et al. (2018). Peters-Burton et al. (2014a) outlined ten characteristics of successful ISHSs from the literature. These components include: STEM-focused curriculum; reform instructional strategies and project-based learning; integrated, innovative technology use; blended formal/informal learning beyond the typical school day, week, or year; real-world STEM partnerships; early college-level coursework; well-prepared STEM teaching staff; inclusive STEM mission; administrative structure; and supports for underrepresented students. Combined, these critical components comprise opportunity structures that advantageously position students on STEM pathways and careers.

Lynch et al. (2018) expanded on this work, introducing four critical components developed inductively through their cross-case analysis of eight ISHSs. These critical components include data-driven decision making for continuous improvement; innovative and responsive leadership; positive school community and culture of high expectations for all; and agency and choice. Although the substance remains the same, Lynch and colleagues also slightly modified the terminology of several critical components from the Peters-Burton et al. (2014a) study. Fig. 2 offers a visual overview of these ISHS critical components and their link to STEM school outcomes.

Fig. 2 STEM school critical components and their links to STEM school outcomes.

Critical components explained

In this section, I offer a short description of the critical components of inclusive STEM-focused high schools. Given that students choose to attend these schools, they harbor a sense of purpose that aligns with the school's STEM focus and recognize the challenges involved with a rigorous curriculum. The critical component of a college-prep, STEM-focused curriculum for all (Lynch et al., 2018; Peters-Burton et al., 2014a) entails rigorous courses in all four STEM disciplines that support STEM pathways and careers. The extent to which ISHSs practice integrated STEM, however, is unclear, although they often have project- or problem-based learning approaches that support the interdisciplinary connections and development of 21st century skills such as collaboration, critical thinking, creativity, and leadership (Holmlund et al., 2018). Reform instructional strategies include project- and problem-based learning and performance-based assessments that encourage students to take ownership of their learning.

ISHSs are well-resourced, including technology that supports students in research, modeling, and STEM-related social networking (Vaval et al., 2019). In order to support students in meeting rigorous expectations, ISHSs offer tutoring, advisories, and special classes such as college and career readiness. Learning extends beyond the school day, with rich, informal STEM learning opportunities, including mentoring, apprenticeships, internships, after school programs, and field trips, furthered by community, business, and industry partnerships. Schools may participate in Science Olympiads and science fairs.

STEM teachers and professionalized teaching staff are considered highly qualified due to their certifications, advanced STEM content knowledge, and/or practical experience in STEM careers. Teachers are supported with professional development, collaboration, and interactions with STEM professionals and have high expectations for their students (Means et al., 2017). Moreover, due to liberties from the district to address innovative goals and partnerships with organizations that offer expertise, leadership, and resources, administration is flexible and autonomous. Leadership is also responsive and innovative and proactively addresses the needs of teachers, students, and the larger community, through open communication and data-based decision making. Overall, ISHSs possess a culture of continuous improvement and high expectations for students and staff who "feel a sense of personal, intellectual, and socio-emotional safety" (Lynch et al., 2018, p. 718).

Review of the STEM school literature

In this section, I review the current peer-reviewed articles on STEM schools. Apart from the characteristics of STEM schools detailed in the previous section, the existing body of STEM school studies primarily centers on STEM school effectiveness, measured in terms of outcomes. While there is still much to be learned about their effectiveness, extant research offers initial results. In the following sections, I discuss the literature on selective and inclusive STEM school outcomes.

Selective STEM school outcomes

In a study of selective STEM schools that examined students' post-graduation plans, 75% of participants expressed a desire to go to college and 40% planned to obtain doctorate degrees (Thomas, 2000). Slightly over half of the students who graduated from these schools majored in science and about 10% majored in mathematics in college. Likewise, according to a national survey of alumni of 25 selective STEM schools, almost 50% of students graduated with a STEM degree (Subotnik et al., 2013). Students also demonstrated positive outcomes on state assessments, college entrance exams, and end-of-course assessments. In another study, students in selective STEM schools were more likely to report earning a STEM-related degree if their teachers asked questions with pre-determined answers, made connections with other content areas, focused on deep understanding of complex content, accepted criticism of their ideas, and reinforced self-confidence in STEM activities (Almarode et al., 2016). Moreover, participation in an internship or mentorship experience were additional characteristics positively associated with earning a STEM-related degree. Overall, studies of selective STEM school outcomes have been positive with respect to post-secondary STEM achievements and aspirations.

Inclusive STEM school outcomes

It is argued that ISHSs support minoritized students through curricular, instructional, and organizational opportunity structures that promote STEM knowledge and skill development and positively position students on STEM pathways (Lynch et al., 2018). An emerging and growing area of research on ISHSs offers some insights into student outcomes. In the sections that follow, I detail the ISHS research on student course-taking patterns and experiences, student achievement, student aspirations and interests, and effectiveness of addressing disparities.

Rigorous course-taking patterns and experiences

Using survey data, Means et al. (2016) compared ISHS students' high school experiences and achievement with that of students in non-STEM schools in North Carolina. Students who attended an ISHS were more likely to complete pre-calculus and chemistry in high school. Similarly, Saw (2019) found positive associations between ISHS enrollment and student completion of advanced level math courses in high school. Another study that examined 94 ISHSs and almost 10,000 students found positive effects on students' completion of key STEM courses and participation in STEM activities as well (Means et al., 2021).

Likewise, instrumental case studies have confirmed reform-oriented instructional approaches in ISHSs (Lynch et al., 2017; Morrison et al., 2015; Slavit et al., 2016). For example, graduates from T-STEM academies in Texas described their teachers as having extensive interdisciplinary knowledge. They also mentioned inquiry and project- and problem-based learning experiences that allowed for group work and real-life, hands-on learning applications (Bicer et al., 2020). Students felt supported by tutoring programs to meet the rigorous expectations of Advanced Placement courses and dual credit opportunities. Authentic research collaborations with university professors and internships in key industries were also highlights of their experiences.

Moreover, a cross-case analysis that explored students' engineering education experiences indicated that students learned key components of engineering such as design thinking, engineering habits of mind, and communication skills, although other elements such as the tension between optimization and constraints, systems thinking, and mathematical modeling were lacking (Peters-Burton and Johnson, 2018). Despite limited resources that were budgetary, technological, and logistical in nature, Wayne School of Engineering (WSE), a rural high school in North Carolina, maintained increased rigor of courses and connections with outside partners (Peters-Burton et al., 2014b). In these ways, a majority of the ISHS critical components that address rigorous, college-level STEM experiences and supports were present.

In contrast, some ISHS studies have detailed an erosion of opportunity structures as schools have attempted to meet accountability demands, including raising state exam scores and graduation rates while facing multiple challenges simultaneously (Eisenhart et al., 2015; Weis et al., 2015). For example, gatekeeping courses such as chemistry, physics, and pre-calculus—that would positively position students on STEM pathways—were no longer offered at an ISHS in the Weis et al. (2015) study by the 3rd year. Instead, only repeater and remedial math and science courses that focused heavily on standardized test preparation were provided. In an ISHS where these courses were still offered, they were found to exist in name only; that is, only Algebra I and II content were covered in a pre-calculus course. Moreover, Stehle and Peters-Burton (2019) conducted a mixed methods study that examined the extent to which student work samples and teacher lesson plans from seven exemplary ISHSs engaged in 21st century skills. Results indicated that out of 60 lessons, 50 included instruction on 21st century skills, but most were at an introductory level. Lesson plans for grades 11 and 12 tended to involve higher-order skills. Overall, there is much to be explored with regard to in-depth, instructional practices.

Achievement

Another area of the ISHS literature has focused on student outcomes such as achievement on standardized assessments. Scott's (2012) multiple case study of ten high schools revealed that students were more likely to score higher than the state average in assessment areas of math, science, and English. Also promising, ninth grade students at T-STEM academies performed slightly better on mathematics state tests, and 10th grade students performed slightly better on both mathematics and science state tests (Young et al., 2011). In a study in which academic and attendance outcomes of the first inclusive, integrated STEM high school in the United States were explored, not only were student attendance rates higher, but more than two-thirds of students were deemed college-ready on the ACT as compared with about 40% in the district (Johnson and Sondergeld, 2020).

There have also been mixed or negligible achievement results. For instance, findings from Means et al. (2021) revealed a small positive impact on science test scores for students attending ISHSs, particularly economically disadvantaged students, although there were no discernible impacts on math test scores. In another study, no significant student gains were found in reading, mathematics, and science from attending the inclusive Texas STEM schools; however, the study only covered the first 4 years of the academies (Sahin et al., 2015). Results from Saw (2019) indicate that Texas ISHSs had no impact on student test scores in math and science. Additionally, Gnagey and Lavertu (2016) found that attendance during the first 2 years of high school in Ohio ISHSs can have a negligible or negative effect on academic achievement. In some ISHSs, there were achievement gains in science courses, but these gains were accompanied by lower performance in non-STEM courses.

STEM interests and aspirations

Research also exists with respect to students' STEM interests and college and career aspirations. Means et al. (2016) found students to be more interested in science careers and involved in STEM extracurricular activities, which were positively associated with students' attendance and GPA. These findings are consistent with that of the LaForce et al. (2019) study in which students had positive attitudes toward science and STEM careers, and those with higher ratings of supportive relationships with the school community also reported significantly higher ratings on science ability beliefs (LaForce et al., 2019). However, as students progressed through the grade levels, their science attitudes declined.

Alternatively, results of another study revealed that students who participated in key STEM courses and self-selected STEM activities identified more strongly with math and science as seniors, and they were more likely to be interested in one or more STEM careers (Means et al., 2021). Furthermore, all participants in the Bicer et al. (2020) study who had completed 1–3 years of undergraduate education when the study was conducted had passed their college courses. They also majored in STEM areas of expertise including engineering, mathematics, computer science, molecular biology, animal science, and genetics. Overall, ISHSs “do typically enhance STEM coursetaking and career interest across a range of different state contexts” (Means et al., 2021, p. 17). In these ways, the possibilities of ISHSs extend beyond entry into STEM majors and careers and also potentially promote science dispositions and affective factors that could facilitate lifelong, sustained engagement in STEM.

Racial/ethnic, economic, and gender disparities

Means et al. (2021) found that ISHSs attracted students from groups underrepresented in STEM, with 63% of students from low-income homes and 69% classified as underrepresented minorities. Provided that ISHSs are designed with a particular mission to support underrepresented students in STEM, studies have also examined whether these schools have been effective at reducing persistent racial/ethnic, economic, and gender disparities. In one study, high school graduation rates for racialized minorities and low-income students improved, given that the math performance of low-income students in ninth grade increased, and female students were more likely to complete more AP or IB credits in math (Saw, 2019). In another study, female Hispanic and African American students in North Carolina and Texas ISHSs were more likely to take advanced STEM courses as compared with students in traditional schools (Means et al., 2017). In both states, 12th grade females also expressed greater interest in STEM careers if they attended an ISHS.

In contrast, LaForce et al. (2019) found that traditional race and gender gaps persisted, and Black and Hispanic students fell below White students in attitudes and achievement. While females consistently demonstrated higher GPA than males, they had less positive attitudes toward science and STEM careers. As the researchers posited, “While STEM schools seem to be successful at providing a diverse body of students with access to an environment that promotes STEM success, access alone may not be sufficient to eliminate gaps in science attitudes and GPA across race/ethnicity and gender identity” (LaForce et al., 2019, p. 12, emphasis in original).

Despite claims to equity and fairness, STEM schools in Chicago have given cover for school closures, the displacement of Black and Latinx communities, and the reification of discriminatory tracking, while White middle-class families and corporate interests have been prioritized (Morales-Doyle and Gutstein, 2019). Black students have been drastically underrepresented in the most desirable, selective-enrollment Chicago STEM schools and overrepresented in schools that have steered students toward working-class jobs needed for Chicago labor markets. In fact, predominantly Black schools in Chicago offered zero science or mathematics dual-credit options and emphasized workplace skills over science. This reality contradicts the touted “college-prep STEM curriculum for all” and pathways for lucrative STEM careers (Morales-Doyle and Gutstein, 2019). As documented in the Eisenhart et al. (2015) and Weis et al. (2015) studies, the STEM school movement has also been a driver of inequality.

Summary of findings

Overall, research into STEM school outcomes is in its early stages. Given that STEM schools are relatively new, reform effects can take 5 or more years (Borman et al., 2003). Apart from identifying distinguishing characteristics of these schools, existing literature on STEM schools consider their effectiveness, based on factors such as course taking patterns and experiences, achievement on standardized tests, STEM interests and postsecondary aspirations, and reducing educational disparities. Though there are mixed results on the effectiveness of STEM schools, for the most part, studies signal slight positive outcomes on science and math, attendance, high school graduation rates, and STEM college and career pathway interest (Bottia et al., 2018; Erdogan and Stuessy, 2015; Means et al., 2017, 2016; Wiswall et al., 2014). As Means et al. (2017) concluded, “The ISHS data suggest that regardless of their demographic background, students who have an interest in STEM can benefit from a rigorous STEM-focused curriculum if provided with the kinds of instruction and supports emphasized in the ISHS model” (p. 17). There is some promise, although scrutiny and vigilance are necessary, given the warnings from other cases (Bullock, 2017; Eisenhart et al., 2015; Weis et al., 2015; Morales-Doyle and Gutstein, 2019).

When it comes to elementary, middle, charter, magnet, and private STEM schools, there is a paucity of research, and their effectiveness is less promising. In a study of nine STEM-focused charter schools and two STEM-focused magnet schools serving elementary-aged students, Judson (2014) found no effect on achievement in math, language arts, and reading in the magnet schools and some positive effects in the STEM-focused charter schools. Additionally, an examination of Catholic kindergarten to eighth grade STEM-focused schools revealed tensions in navigating dual Catholic and STEM-focused identities (Kloser et al., 2018).

What is more, the impact of STEM-focused CTE programs remains largely unexplored. While there are no specific studies of STEM-focused CTE schools, there are studies of STEM CTE course-taking outcomes, which have produced negligible or mixed results. For example, Gottfried and Sublett (2018) found that students with learning disabilities were less likely to take applied STEM courses in high school as compared with the general population, while enrolling in applied STEM courses was not associated with taking advanced math and science coursework later in high school.

Upon examination of CTE-STEM course enrollment in Texas, another study found a larger gender disparity in advanced science courses than advanced math courses, and racial/ethnic and gender disparities worsened over the years (Yoon and Strobel, 2017). Moreover, Freeman et al. (2021) found no evidence that earning more Applied STEM Career and Technical Education (AS-CTE) credits in high school influenced college enrollment patterns or major selection for students with learning disabilities. However, students with learning disabilities who earned more AS-CTE credits in high school were more likely to seriously consider and declare AS-related majors in college. For low-income students as compared with their non-STEM-CTE counterparts, taking STEM-CTE courses has been associated with higher school engagement (Plasman et al., 2021). Overall, these varied results warrant additional exploration.

Going forward: a vision for STEM schools of tomorrow

STEM schools are considered full of potential and promise for STEM reform efforts. As [Morales-Doyle and Gutstein \(2019\)](#) noted, “The cachet of STEM education is related to the high status and pay of the associated careers and is also connected with the prestige of canonical scientific and mathematical knowledge” (p. 533). At this juncture, a majority of STEM schools have been around for less than 10 years. Accordingly, STEM school educational research is still in its infancy. While much has been learned about their common features and effectiveness, gaping unknowns remain. In this section, I offer some suggestions for further research and a vision for STEM schools of the future.

The current empirical literature base on STEM schools is dominated by United States contexts and as such, further examination into STEM schools in other international contexts would be fruitful, especially given the global rise of STEM. A lot can also be learned from studies of STEM schools across grade levels, including elementary and middle schools. In fact, the 2010 PCAST report called for 80% of the 1,000 new STEM-focused schools to be elementary and middle schools. A range of other school contexts should be explored as well, from rural to private and CTE, among various models including residential and early college programs.

Existing ISHS studies have offered snapshots of classroom life due to participant observation spanning two-to four-day time frames and across courses in different disciplines and grade levels ([Bruce-Davis et al., 2014](#); [Eisenhart et al., 2015](#)). As such, in-depth, qualitative studies that engage continuous observations that can further understandings into organizational, instructional, and cultural practices are imperative ([Tripp, 2021](#)). This nuanced contextualization will be key to understanding distinctive educational practices, the fidelity and effectiveness of implementation, and navigation of tensions involved with accountability and other pressures that stakeholders might face ([Nasir and Vakil, 2017](#)). Deeper interrogation into critical components such as STEM school leadership and innovative, integrative technology use are also valuable ([Lynch et al., 2018](#)).

Another arena for prospective research involves an expanded view of STEM school outcomes, based on multiple, varied measures of assessment that more authentically evaluate what students know and are able to do and are informed by culturally responsive, relevant, and sustaining approaches ([Gay, 2010](#); [Ladson-Billings, 2014](#); [Paris and Alim, 2017](#)). As the [NRC \(2011\)](#) contends, “Test scores, however, do not tell the whole story of success” (p. 6). Outcomes such as shifting STEM identities, motivations, feelings of belonging, and attitudes toward STEM among the STEM school community—along with the effectiveness of these schools in redressing opportunity gaps ([Milner, 2012](#))—should be considered as well. In what ways might joy, community, criticality, and commitments to morality and humanity be fostered and measured ([Morales-Doyle, 2019](#); [Szostkowski and Upadhyay, 2019](#))? In what ways might the longstanding stereotypes about science and STEM be challenged and overturned in STEM schools ([King and Pringle, 2019](#))? Do students and communities feel equipped and empowered to tackle authentic, socioscientific issues relevant to their everyday lives? Perspectives from multiple stakeholders, including school leaders and family and community members, to multilingual students and students with disabilities should be explored.

Efforts to understand school- and student-level contextual conditions surrounding outcomes are essential as well. Longitudinal investigations that follow STEM school students across elementary, middle, and high school—as well as post-graduation—would be ideal. Such studies would offer more insights into the supports that all stakeholders in STEM school communities need to succeed—in addition to the assets that they bring. This research agenda would inform a more concrete direction for improving STEM instruction and learning in the areas of design, implementation, and evaluation of STEM schools.

Equity considerations

It is well known that there are persistent racial/ethnic, gender, socioeconomic, and disability-based inequalities with respect to participation in STEM fields. Disparities also exist in rural schools with regard to advanced opportunities such as college-level coursework ([Assouline et al., 2017](#)). In fact, [Saw and Agger \(2021\)](#) found that there were fewer STEM opportunities for rural and small-town students in the United States, which adversely affected STEM career aspirations, academic preparation, and postsecondary STEM participation.

While parity in participation is important, equity in STEM is more than “simply access or exposure;” it is also about “issues of knowledge production, epistemology, culture, and power” ([Nasir and Vakil, 2017](#), p. 378) which have fueled these disparities. Indeed, the culture of STEM and the spaces in which STEM opportunities have existed often mirror the interests, values, and experiences of the dominant culture and are often unwelcoming to minoritized groups as a result. Instead of reinscribing traditional White male cultural norms and Eurocentric, positivist teachings of STEM, it is important for all stakeholders to recognize and seek “multiple perspectives, knowledge frames, and approaches” ([Mensah and Jackson, 2018](#), p. 32). STEM should be considered with “local knowledge, stories, narratives, traditional practices, wisdom, and collective intuitions” ([Bascope and Reiss, 2021](#), p. 2). Moreover, STEM alone cannot be a panacea to all of society’s problems. Rather than portray STEM as “apolitical and inherently good” ([Hyttén and Stenmagen, 2020](#), p. 28), STEM education should afford students opportunities to unpack the ways in which STEM can and has been used to perpetuate both benefit and harm.

As [Bullock \(2017\)](#) noted, “it is not possible to achieve an equitable future without correcting the discriminatory policies and practices that make up the fabric of schooling” (p. 637). Without critically interrogating embedded assumptions and power dynamics in the design and implementation of STEM schools, without intentionally integrating culturally and linguistically

sustaining, anti-racist, and decolonizing approaches, inequities have and will continue to endure (hooks, 1994; Paris and Alim, 2017). STEM education should prepare and empower marginalized students to critically contend with issues relevant to their lives and focus on ways to address them in solidarity with one another (Morales-Doyle and Gutstein, 2019). Inclusive STEM school models have promising approaches, yet beyond adhering to their design with fidelity, opportunity structures of all dimensions must be reexamined and monitored such that they become centered around students' identities, nurture competence, raise critical consciousness, and cultivate joy, empowerment, and community (Tripp, 2021). In these ways, with an aim of continuous improvement and in the spirit of collective interdependence, STEM schools of the future can be welcoming, stimulating, and nurturing hubs of excellence for everyone.

Introduction

Virtual reality is a part of a family of technologies designed to create a synthetic or artificial environment. Technologies related to virtual reality include augmented reality, mixed reality, and “flat” two-dimensional environments. Virtual Reality (VR) is defined as a three-dimensional synthetic digital environment which allows multiple degrees of freedom for the user to interact with the environment and engage in immersive interactions within these environments. While there are several types of digital environments which are related to VR e.g., Augmented Reality, Mixed Reality, etc., VR is the only digital environment which is fully synthetic and completely immersive.

Immersion is one of the most critical characteristics of VR and related technology. It is immersion or the ability to become emotionally, cognitively, and behaviorally engrossed in the environment which creates the specific affordances of VR that promote the learning outcomes seen when using VR. Environments within VR may be ultra-realistic and almost indistinguishable from real world interactions. Lamb among others in multiple studies has illustrated that psychophysiological and neuro-cognitive responses of persons using VR environments very closely mirror the responses of the same person in similar real-world environments (Lamb et al., 2018a,b,c, 2021; Minderer et al., 2016). It is the similarity of the cognitive and sensory responses that helps to facilitate STEM learning using VR by triggering the same cognitive and affective responses as if they were in the real-world.

While there is tremendous value in using VR to explore realistic environments which may otherwise be unreachable by the user, VR has even greater value in the exploration of environments which are not typically encountered in the real-world. These environments could include visualizations and interactions within microscopic worlds e.g., at the atomic scale, interactions within environments which would be dangerous in the real-world e.g., walking at the bottom of the ocean, or interactions with environments which may be otherwise unreachable such as the surface of another planet. In many ways, VR is an important tool to provide experiences and access to almost any environment and interaction imaginable. The broad applicability of VR, coupled with the experiential nature of VR, makes VR a potentially transformative tool in STEM Education and a key area of exploration for educational researchers. The immersion, experiential nature, and ability to manipulate the environment drives much of the successes seen with VR and similar tools.

Current foci in STEM Education disciplines require students to develop sophisticated abstract understandings, manipulate multiple ideas simultaneously, integrate complex and abstract ideas, and align observations in order to learn content and practices in STEM disciplines. However, some of the opportunities to engage in environments which promote these activities are impossible to replicate in educational settings. To address the teaching and learning of complex and abstract ideas, educators focus on pedagogies which stress sense-making through connections to prior experiences and extrapolation to observed phenomena through mental models. These mental models often use representations and simplifications to help ground understandings in concrete and discrete terms particularly for younger students. The use of concrete and discrete terms and ideas links the abstract concepts in STEM content to student everyday experiences. The everyday experiences become the

building blocks of the mental-models students use to understand the world around them. From these mental models students then explain the world around them and generate understanding (Johnson-Laird and Khemlani, 2017). To this end, students in all disciplines, but in STEM disciplines specifically, learn from experiences by interacting with practices and content through their senses. The technologies used to create VR environments replace the stimulus from the real-world with digital stimulus which is more able to be personalized by the content creators and even the student. The personalization of the stimulus allows the student to individualize their experiences and promotes development of mental models which are more easily accommodated by the student. The mechanism by which this is thought to occur is cognitive priming and affective priming for learning (Lamb et al., 2015a). In other words, VR sets the conditions for the priming of specific neurocognitive systems by allowing the student a greater degree of control and immersion which improves learning opportunities.

Virtual reality in STEM education

The approaches and reasons to use VR in STEM education are often similar to the reasons an educator may use a two-dimensional, computer-based simulation. These reasons include the presence of a soft-failure environment, reduction in the cost of materials, commonality of experiences across students, and the ability to provide experiences not otherwise available (Protopsaltis and Baum, 2019). However, in addition to the reasons identified for using a computer-based instructional approach, VR offers additional affordances beyond these. VR has the potential to create individualized and custom learning environments which can accommodate the distinctive needs of the learning. Through this immersion and individualization exploration and discovery are promoted, ultimately this will motivate, encourage, and excite students about STEM discipline content increasing engagement with the content. The learner in the VR context can take part in the learning environment with a sense of embodiment which is not available in flat screen interactions. Conceptually, VR provides the following affordances: (1) VR is a first-person concrete representation of STEM discipline phenomena and ideas that can align to authentic content and practices within STEM disciplines. When combined with specific pedagogies VR helps students to learn complex and abstract material. (2) VR provides opportunities for experiences that may not be obtained by learners in other ways due to cost, complexity, or risk. (3) VR makes use of first-person embodied experiences, and this form of experience tends to make up the majority of our non-classroom-based interactions related to our environment. In contrast STEM classrooms, particularly for older students, tend to focus on third-person abstract and representational experiences reducing the construction of understanding and sense-making.

From an understanding construction and sense making perspective, VR and related technologies promote learning through the ability of the user to manipulate the scale of the experiences and move from the microscale to the macroscale. Through transformations at each of these scales, new sources of information and understanding may be experienced. VR is one of the only tools (outside of actual experiences) that allow students to learn from non-symbolic, immersive, first-person experiences.

VR as a tool for learning allows students to access the symbol systems associated with the content and practices of STEM disciplines in ways that work the best for them. VR promotes success in learning for students who may need to make use of alternative means of learning because written content does not allow them to access the content in a meaningful way. Pedagogically VR provides new forms and methods of content visualization and sensory stimulation. This occurs by drawing on not just the strengths of visual representations but the ability of VR to integrate multi-modal and cross modal cues related to the content reducing cognitive demand (Lamb et al., 2015a,b). VR also provides multiple alternate methods for content and practice presentation alongside the ability to manipulate the content in three-dimensional space. For example, a student may hold the planet Jupiter and Earth in their hand and directly compare the sizes of the planets. This allows the student to conceptualize the true proportions of the planets at a scale that makes sense to them. VR can also be used to clarify features, processes, and activities using novel means such as data rotations or other “physical” manipulations in VR environments. These manipulations allow close-up examination of an object to understand subsidiary structures, observation from a great distance to see overall patterns, and observation and examination of areas and events across time or that are unavailable by other means.

From an affective perspective, VR motivates and engages students by providing perspectives which are engaged with in novel ways. The first-person nature of VR requires interaction and encourages active participation in learning rather than passive participation as students engage with the experiences. Some types of virtual reality such as multi-user VR encourage and require collaboration providing socialization and interaction with others in ways that are not available in the real-world or on flat screens. Differentiation of experience and customization of learning opportunities in VR allows the learner to proceed through an experience at their own pace and in locations outside of the classroom. Importantly these features of VR allow students with differences to participate in learning environments which if they were in the real-world may limit their interactions. Because of the symbolic and representational nature of VR it can also transcend language barriers allowing students with English as an L2 to make sense of phenomena in their own way. The pedagogical affordances of VR in summary are: (1) visualization and reflection; (2) an alternate method for presentation of material; (3) learning in contexts impossible or difficult to experience in real life; (4) motivation, collaboration, adaptability, and differentiation; and (5) evaluation and assessment occurring in near authentic environments and with near authentic activities.

Immersion and interactivity two key factors

To fully take advantage of the affordances of VR two forms of immersion must be present: sensory immersion and psychological immersion. These two distinct forms of immersion help to create successful learning experiences within VR environments by helping to create physical sensations and psychological connections within the VR environment (Lamb and Etopio, 2019a,b). Sensory immersion occurs when students move or interact in some “physical” way within the VR environment. The visual, auditory, and kinesthetic feedback from the digital environment to the student’s sensory memory systems creates the immersive illusion that the student experiences as being bodily present in the environment. To accomplish sensory immersion visual, auditory, or haptic devices related to the environment must respond in a realistic, timely, and meaningful way, making use of inputs from the user. Ideally the sensory experiences are physiologically the same as those found in real-life thus triggering the same neurocognitive systems (Ferreira and Mavroidis, 2006). When VR environments are developed with both sensory immersion and pedagogical approaches in mind, users can interpret visual, auditory, and haptic cues to gather information and move toward specific learning outcomes (Lamb et al., 2018a,b,c; Lamb, 2016; Liu et al., 2020).

While sensory immersion results from engagement with the physical senses, mental immersion refers to the “state of being deeply engaged” psychologically within a VR environment (Huang et al., 2010). Mental immersion is critical to the success of VR as with on sensory immersion there is still the understanding that the environment is not “real,” and this may reduce the experiences and not trigger the appropriate neurocognitive systems. While sensory immersion is used to develop the mental immersion, mental immersion is how a VR system engages the students in learning about STEM discipline content. Essentially, the user “forgets” they are in a digital virtual environment and the interaction then becomes embodied. For VR environments designed for learning related to STEM disciplines, a significant marker of the success of the environments is predicated upon how involved the user becomes within the learning environments. One potential way to measure this marker in real-time is through psychophysiological and neurocognitive measurements which when combined with machine learning classification can adapt the environment in real-time (Lamb et al., 2022).

A second key feature of VR that helps to distinguish it from other educational technologies, particularly flat screens, is the real-time interactivity and responsiveness in digital stereoscopic three-dimensional environments. Real-time refers to the ability to make use of data with little (millisecond) or no delay. The fluidity of the interactivity with the digital environment helps to create the immersive experiences which are the fundamental attraction of VR for educators. VR as a system can interpret gestures and other actions and respond as if the digital environment is a real-life physical environment. The responsiveness occurs with relatively little lag resulting in a more authentic, true-to-life experience for the student. Interactivity coupled with the ability of VR to respond realistically promotes the sensation of sensory immersion by responding to user behaviors with actions on the screen. Auditory, haptic, and tactile inputs (Klatzky et al., 2014) allow users to not only interact visually with the environment but to manipulate (i.e., touch and feel) graphic objects on the screen. The ability to manipulate items sets VR apart. In short, VR technology is well suited to convey difficult abstract concepts, practice skills, and interact in complex environments due to the visualization, fluidity, interactivity, and immersion of the environment (Psotka, 2013; Lamb and Firestone, 2018). Importantly because the VR environments are fully digital, they can be programmed and shaped in any way necessary to promote learning. When educators design an environment for delivery of complex concepts, it is necessary to ensure the presence of the three features of (1) interaction, (2) immersion, and (3) authenticity in the learning environment. Fig. 1 illustrates the continuum of the relationship between interactivity and immersion as it relates to VR and related technologies. Authenticity is simply the need to make the interaction and environment as realistic as is needed to trigger the neurocognitive and sensory systems to promote learning (Fig. 2).

Fig. 1 Overview of VR in relation to other similar technologies.

Fig. 2 Example VR laboratory views available to the student.

Use case

This use case seeks to explain barriers and affordances related to content learning and immersion when using VR designed to replicate a hands-on laboratory environment for educational purposes. The primary means for data collection associated with this use case is a combination of multiple-choice survey combined with open-ended interviews.

VR laboratory environment

The VR laboratory used in this study was developed as a means to supplement and replace existing laboratories in the biology and chemistry. The VR laboratories are fully digital and do not make use of 360-degree camera footage. The VR classroom was experienced using a standard HTC Vive Virtual Reality headset. The HTC Vive was not specifically modified for the interactions apart from the use of noise canceling headphones. The VR headset allows a room scale of $12' \times 12'$ virtual environment with 6 degrees of freedom. The screen resolution was 2160×1200 and uses a refresh rate of 90 Hz. The headset equipment consists of the headset, two wall-mounted sensors for bodily positioning, and handheld motion controllers to position the hands. The computer used to generate the environment was a Dell G5 Gaming Desktop with a virtual reality ready video card.

Two primary views of the laboratory were available to the students. The first view is an overall view of the laboratory used to access various pieces of equipment within the laboratory. Students interacted with this view by using the thumb controller to move an avatar around the laboratory and to position the avatar at a specific bench for work. The second view available to the student once they reached a specific bench area was a first person view with two hands. The two hands were controlled by the handheld controls. The digital hands could pick-up items, move items, pour items, and otherwise are used to interact with the environment. In addition to using the controllers to move the hands students could also walk short distances while at the bench to reach other items. Sounds associated with the use of various laboratory equipment were also present in the environment. Overall, the environment is considered an open-world sandbox type environment. Meaning that the students could move around and complete tasks in any order. It should be noted as with real-life laboratories if the student did not appropriately follow the protocols the laboratory did not produce results. [Fig. 1](#) provides a visual depiction of the laboratory.

For this use case, five laboratories were selected for study: three chemistry and two biology. The specific five laboratories were selected by classroom instructors as they felt these topics were most aligned with the needs of the course. The three chemistry laboratories covered the topics of acids and bases (26 min), atomic structures (34 min), and basic chemistry thermodynamics (42 min). The biology laboratory topics consisted of animal genetics (53 min) and antibodies and blood type (37 min). [Table 1](#) provides a summary of the five laboratories and the specific concepts covered. During the completion of each laboratory the students were able to keep notes about the results, redo experiments as often as they like, and upon completion were assessed using a multiple-choice assessment.

Table 1 Overview of topics covered in this use case.

<i>Laboratory</i>	<i>Concepts covered</i>
Acids and bases	Measure of pH and evaluation of mixtures of acids and bases.
Atomic structure	Properties of element samples, atoms, and ions. Prediction of properties of elements based upon periodic table position.
Basic chemistry thermodynamics	Bomb calorimetry, concepts of thermodynamics, renewable energy.
Animal genetics	Mendelian inheritances, gene linkage analysis, mutations, and gene expression.
Antibodies and blood type	Antibodies antigen interactions, ABO and Rhesus blood groupings, risk for Rhesus disease, blood transfusions.

VR and knowledge generation

VR in the context of this study is thought to construct knowledge through experiences and provide the ability to examine phenomena at multiple scales. The selected laboratories were developed with a knowledge construction approach using a user experience construction lens. By providing a fully immersive environment with the sights, sounds, and tactile feedback the intent was to fully simulate a laboratory experience. To accomplish knowledge construction through a VR environment, VR designers must create activities which allow learners to take an active role in their learning through fluid and immersive environmental interactions (Vygotsky, 1967). The intention of creating a fluid and immersive environment is to sufficiently simulate a laboratory experience such that students can connect current information with prior knowledge (Vygotsky, 1967). To accomplish this connection the environment and specific design elements such as the interactions with the laboratory equipment, the concepts explored, and the practices associated with the content must be sufficiently realistic. Sufficiently realistic means that the environment is sufficiently real enough to trigger the same neurocognitive response as would be triggered by the real-world equivalent action or environment. The realism and responsiveness of the environment plays a critically important role in learning (Kintu and Zhu, 2016). When responsiveness and sufficient realism are not present this can lead to affective priming (e.g., Lamb et al., 2015a,b) and ultimately to frustration and lack of interest in completing the laboratory. By providing realism and responsiveness through immersion and interactivity, students have the opportunity to directly apply their practices and content to a context which provides meaningful feedback and practice. To successfully learn, students must be allowed to directly apply their knowledge to realistic and authentic contexts, engage in failure, and explore their successes and failures in a safe low consequence environment without the structures of the experience e.g., the VR system complicating the interaction (Stefaniak et al., 2020).

Technologies such as VR allows learners to engage in experiential and exploratory learning within low consequence environments. In the case of these laboratories the students could redo the laboratories multiple times. VR fills a core need within STEM education; that learning should be experimental and experiential (Long et al., 2020). Using VR, the educator's role is to help shape and facilitate the learners' experiences and understand how the surrounding digital environment promotes or impedes necessary learning (Ebenezer et al., 2020). Considering this responsibility, it is important that educators consider the user experience when implementing VR in the classroom. Within the user experience the educator should focus on how the content and practices are developed in VR, and how the learner's control of the learning process impedes or assists their learning and task completion. Therefore, VR designs for education must assume that not all learners can formulate their current knowledge as discrete concepts and tie it to experiences and authentic tasks. Designers must scaffold and provide other adaptive supports which meet the needs of varying levels of learners. A user experiences centered approach to VR provides learners more freedom to select and coordinate their learning processes and to construct knowledge through these means. User experience centered constructivists emphasize the design of learning environments rather than instructional sequences and focus on the individual differences of the learner. The learning environments should provide real-world, case-based environments for meaningful and authentic knowledge construction with minimum system friction.

In the case of VR for STEM education, it is important to not only focus on the user experience but also provide educational means and opportunities to examine questions, claims, and evidence. The inclusion of the pedagogical component is a key differentiator between user experience researchers outside of education and user experience researchers within educational contexts. Current research related to educational technology suggests that user experience centered constructivist principles fundamentally underlie learning in an VR environment (Levin and Tsybulsky, 2017; Lamb and Etopio, 2019a,b; Lamb et al., 2018a,b,c). User experience centered constructivist learning in VR has multiple characteristics: (a) the learning involves the exploration, internalization, and discovery within the prebuilt, interactive, immersive representation of the real-world, (b) engagement with prior knowledge, (c) learning processes that allow educators to examine VR features which support learning, and (d) deep consideration of how the user interface and related software and hardware influences learning outcomes and success.

Fig. 3 Neurocognitive comparison of VR and real-life activities. Images supplied by the East Carolina University Neurocognition Science Laboratory.

VR allows learners to interact with simulated environments in real time and engage with soft failure (Nelson, 2016). VR also offers greater sensory cueing and multimodal feedback to enable the transfer of concepts learned in VR into real-world understandings related to the VR topics (Smith et al., 2020; Lamb, 2016). For example, learners can view 3D objects from multiple representations, viewpoints, and scales in addition to examining and exploring interactions and relationships between the representations and concepts. VR used in more traditional classroom learning environments allows educators to provide experiences which otherwise would not be possible in STEM classrooms (e.g., walking inside of a volcano or seeing a virus infect a cell). Further, immersive environments create a strong sense of presence in the environment, which in turn motivates and thereby causes the learner to cognitively process the learning material more deeply (Shu et al., 2019). A neuroimaging study conducted by Lamb (2019) reveals that when learners interact with VR environments the learners' cognitive systems process the VR immersive environment in the same way that real-world environmental cues are processed (See Fig. 3).

Methods

This use case was based upon focus group discussions and user responses on surveys collected during and after the use of the VR environment in multiple STEM classrooms. One-hundred faculty, representing 300 classrooms, and approximately 1000 students took part in this use case. A subsample of three instructors and three students were randomly selected for the focus groups. The five modules were selected by the instructors based upon alignment to current topics covered in class. VR outcomes were presented as relationships between characteristics of performance, which either impeded or promoted learning for the students in the classroom. Using thematic inquiry, the researchers were able to generate several themes. Data was summarized and used to identify potential relationships between the emergent themes. The VR environment is an immersive 3D problem-based learning virtual simulation of five laboratories. The simulation makes use of realistic 3D animations and interactions to address the hands-on learning goals the instructors have for their class. The VR animations and simulations allowed students, for example, to examine molecular scale representations as learners engage in the performance of experiments to reinforce content learned within non-laboratory components of the class. Upon completion of the VR tasks, instructors and students were asked to attend a focus group and complete a survey.

The areas covered in the focus groups and survey were intended to examine components of immersion and fluidity among the students and instructors through a user experience lens. The areas of user experience are Presentation of Technical information (Immersion), Laboratory Work Mechanics (Fluidity), Learning Outcomes (Immersion), Student Engagement (Immersion and Fluidity), and Ease of Navigation (Fluidity). Instructors and students rated these areas on a 1 (Poor) through 7 (Excellent) scale. Responses to the focus group questions were noted and triangulated with survey responses to develop the themes more fully.

Results

The most common theme emerging from the focus group was a relationship between the technological skill level of the student with respect to the use of VR and the student's history with online learning management software. Results also illustrate that a significant technological barrier existed. This technological barrier increased the difficulty and utility of VR when considered for the full implementation in the replacement and supplementing of hands-on laboratory work. This is as opposed to conceptual barriers meaning that the ideas associated with the presentation of content and practices in this VR environment met the needs of the students, but the

user experience in terms of the immersion and fluidity are not fully developed and require a technological solution e.g., less lag in the response, more articulation with the controls, etc. User responses show that instructors and students identified Student Engagement (Immersion and Fluidity) and Ease of Navigation (Fluidity) as the most impactful and positive aspects of the VR experience. The inclusion of the two factors “Ease of Content Navigation” and “Student Engagement” is substantiated because inclusion and specific focus on these two factors of VR experience are shown to be very influential in learning outcomes and the likelihood of persisting through difficulties. Survey and focus group outcomes were integrated to generate themes.

Theme 1, technological savvy

Participants using the VR environment suggested that their savvy with technology played a major role in their acceptance of VR as a means for teaching and learning in STEM disciplines. Particularly because technological savvy allows students to engage with the material in a more fluid and immersive way while ignoring or correcting items which detract from the fluidity or immersion. Technologically savvy students were able to continue through the content despite having to do “on-the-fly” corrections due to glitches within the laboratory. Those with a lack of technological savvy, meaning they had difficulty using input devices, difficulty working with computers, lack of basic knowledge of computer troubleshooting, and did not have high levels of content skills, found working with the VR software extremely difficult. This was because they said it [*the user interface*] when combined with trying to learn new material overwhelmed them. The students could not focus on learning the STEM discipline content because they were too focused on trying to figure out how to correct aspects of the VR environment which did not operate properly. From a neurocognitive perspective, this aligns with previous studies illustrating that there are limited cognitive resources and when threshold levels are exceeded students become frustrated and disengage (Lamb et al., 2018a,b,c). Exceeding cognitive demand levels also reduces a student’s level of motivation to engage with the software due to frustration with the platform.

Theme 2, life like details in the VR simulations

There are two major aspects of the VR experiences which reduced learning outcomes in the VR experience. The first item was the lack of a fluidity and the loss of psychological immersion. Experiences in VR must be mediated through a responsive computer interface and when the interface does not respond in an expected way it creates difficulties in learning. This occurs because the “incorrect” response by the environment must be accommodated. To accommodate the response, the primary cognition used for the process of learning must be reallocated to incorporating the incorrect response breaking the psychological immersion. The second factor was lack of sufficient realism in the VR experience which breaks the sensory immersion. Without sufficient realism, sensory stimuli from the VR system are misaligned creating cognitive dissonances which must be accommodated. Some of the difficulties for the students resulted from a lack of normally anticipated things found in an environment e.g., flipping a switch and nothing happening, or attempting to pick-up an object and not having the object behave as expected. The software also seemed to lack basic science equipment found in traditional life science classrooms such as a microscope, though a microscope is visible in the comprehensive view of the laboratory. However, there was an appreciation for the way safety procedures are represented and incorporated into the software. Students even within the VR environment still had to don and doff personal protective equipment helping to improve sensory and psychological immersion. However, despite these positives, the limitations associated with the simulation equipment, (i.e., the program crashing, lack of tactile feedback, reduced interactivity, and lack of objects to engage in practices) created difficulty for the immersive and fluid aspects of the experience, leading the students and instructors to see the VR experiences as less than life-like and therefore not as good as the physical real-life experiences.

Theme 3, content appropriateness

Content at the appropriate instructional level and that also aligned specifically with learning objectives was a challenge. The lack of alignment reduced the psychological immersion of the VR simulation. Students often became “lost” in attempting to link the presented content to their existing knowledge and expectations. While a positive attribute of the VR experiences is that there was a reduced need for physical space and increased opportunities to engage with the content multiple times, this did not seem to make up for the other areas of concern noted by the instructors and students. Meaning the lack of alignment between the presented content and the expected content reduced the immersive qualities of the VR environment. Thus, the benefit of VR from a cost perspective did not outweigh the lack of sufficient realism and appropriate content. Specifically, the educators felt that practice skill development was deeply hindered by the lack of virtual reality interactivity and sufficient realism.

Theme 4, STEM practice development and difficulty appropriateness

The instructors felt that the VR did not successfully replicate physical world experiences sufficiently. However, the students while agreeing with the instructors, they did illustrate more optimism about the potential of VR. The instructors suggest that may lead to the idea that the inclusion of VR as a supplemental form of instruction. While they see some potential the instructors suggested they need to deeply consider how to make use of VR and specifically they suggested that as it stands the VR environments within this study need improved fluidity and immersion to more fully replace hands-on laboratories.

Discussion

The general assessment of VR for the teaching and learning of STEM content and practices is, that without significant technological improvements VR fails to meet the student's needs associated with studies in STEM disciplines. Specifically, the technological improvements should be focused on increasing the levels of immersion and fluidity, particularly around more sufficiently realistic responses within the environment. The improvements as suggested by students and instructors results from difficulties associated with navigation of the environment (fluidity) and engagement (immersion and fluidity). In the case of this study the VR environment, the learning activities, tasks, and assessments were designed without specific pedagogical approaches embedded into the VR as suggested by [Lamb et al. \(2018\)](#). The lack of alignment of the user experience to specific and explicit pedagogies and learning outcomes led to a disjointed and unstructured learning environment in which outcomes were not able to be anticipated by the users. As instructional designers or educators develop and deploy specific features of VR as a replacement for face-to-face instruction there is a need to consider the student user experience. Importantly they must consider what factors play a role in successful use of the VR environment for learning and how to build immersion and fluidity into the environment to reduce frustration, student training time, instructor training time, and have sufficient infrastructure to support the VR laboratories.

One of the most promising aspects of the use of VR in the classroom is the ability to develop interactive, highly controlled, ultra-realistic, learning environments and experiences which are specifically tailored to those using VR. Appropriate pedagogical approaches involving construction of knowledge in a virtual environment requires that interactions with the VR environment have appropriate levels of fluidity, immersion, and authenticity allowing realistic interactions which trigger the necessary cognitive systems for learning. Without this critical level of fluidity of interaction with the environment the learning process is too difficult to sustain, and the user may not persist. If developed with appropriate levels of fluidity and immersion VR environments can be a reasonable and valuable substitute or supplement for real life experiences ([Lamb and Etopio, 2019a,b](#)). However, as in the case of this study, affective aspects of the interaction, such as frustration, will quickly impede the learning process. Unfortunately, these barriers and impediments develop quickly when working with difficult user interfaces such as the one in this study.

During the VR interactions learners attempted to undertake actions allowing them to put new understandings and new skills into practice, however the attempts to make use of the learned skills in this VR environment were unsuccessful due to the interface and its lack of immersion and fluidity. This lack of success created a negative view of the VR application and reduces the student desire to participate in the environment. In considering future designs and interactions, these interactions must occur in a life-like and measured way. While VR environments may allow learners to acquire knowledge with less difficulty than that of traditional learning processes, poor organization of the environment will have the opposite outcome.

The transfer of skills from the VR environment to real world environments is of critical concern to educators. To accomplish this transition from one environment to the other, VR environments require immersion and realism along with the ability to construct knowledge through interactions. Static VR environments are not of much use and will only act in much the same way a photograph will for learning purposes. This is because of the lack of immersion within the environment.

Immersion and fluidity allow VR tools to be used for similar tasks and reasoning as the tasks and tools found in the real world ([Lamb, 2016](#); [Lamb et al., 2018a,b,c](#)). As a result, VR environments provide rich teaching opportunities and help to improve learners' ability to analyze problems and explore new concepts associated with the environment. The multisensory aspect of the VR technology promotes greater learner immersion by prompting attention and stimulating curiosity. In the case of this VR environment, the multisensory aspect of the environment impeded learning due to the lack of high-quality visuals, poor performance of the application, poor assessment, and poor feedback from the environment e.g., lack of fluidity. That is, features of interaction and immersion will only take a student so far into the environment, if the environment is not fluid and highly responsive. Fluidity and responsiveness are the main characteristics, which maintain engagement with the VR environment ([Lamb et al., 2016](#)).

Conclusion

While this VR environment was missing instructionally important characteristics such as feedback and successive skill development, results from this study provide insight for the exploration of needed characteristics for future iterations of the VR environment. In particular, this study illustrates how to consider inclusion of fluidity and immersion as central themes to the user experience during development. As more students and instructors focus on the use of VR technology and VR applications for education, content will become easier to use and incorporate *a priori* pedagogical approaches with fluid and immersive environments. To promote the use of VR for learning, educators need to understand the challenges students face when using VR technology for instruction for the first time and understand the limitations of the environments rather than counting on the novelty to maintain and promote learning outcomes in STEM disciplines. It is imperative that an instructor making use of VR, keep in mind, that VR is another tool to promote learning and not meant to replace the instructor.

Introduction: learner as the designer

Design is the process of manufacturing products—tangible and intangible—through constant iterations of analysis, synthesis, and evaluation (Gero, 1999). Design, therefore, includes actions ranging from framing problems, setting goals, and making plans to creating (new) products and assessing them iteratively (Koh et al., 2015; Li et al., 2019; Purao et al., 2008; Razzouk and Shute, 2012). In the past, design was regarded as a specialized skill of a few with specific vocations and professions (e.g., fashion designer, game designer, instructional designer). Similarly, in educational contexts, the term design mainly belonged to the educators who designed curricula and learning activities. However, with the recent acknowledgment that suggest “everyone designs and everyone can design” (Li et al., 2019, p. 95), any learner could become agents who design (i.e., devise, create, assess) rather than users of designed products. Accordingly, design thinking—a way of thinking through the process of design—and design practices have been widely used for and by learners to empower their learning experiences, especially in science, technology, engineering, and mathematics (STEM) educational settings (Dym et al., 2005; Li et al., 2019).

We define design-based education (DBE) as educational theory and practice that integrate and transform design processes and design thinking into *learning* experiences, especially for STEM education. DBE has been called with different names such as learning-by-design (e.g., Puntambekar and Kolodner, 2005), design-based learning (e.g., Bekker et al., 2015; Won et al., 2015), engineering design (e.g., Donna, 2012), computational design process (e.g., Kafai et al., 2014), embedded design (e.g., Borge et al., 2020), or making (e.g., Sheridan et al., 2014) and embraces a wide range of curricula and educational programming through which learners participate in hands-on designing for and as part of their STEM learning. Despite its wide range of the activities, DBE often includes iterative, non-linear cycles of analyzing/interpreting, planning, creating, and assessing by the learners. In this article, we demonstrate the concept of DBE and its benefits that align with the 21st century education, review current examples demonstrating innovative movements in STEM education, and discuss suggestions for better applications of DBE.

Foundation and rationale of design-based education

Theoretical foundation of design-based education

While our definition of design-based education (DBE) is centered on the use of design, DBE in essence is based on various theories on learning. DBE is grounded upon socio-constructive and sociocultural perspectives rooted from Vygotsky (Vygotsky, 1978) that consider learning to occur through participation and active construction of meaning when learners interact with their surrounding

Fig. 1 Theoretical foundation of DBE: at the nexus of various perspectives and theories on learning.

contexts (Kolodner, 2004; Rogoff, 1994). Design process can be regarded as mediational means for learners to construct meaning. Incorporating design process into the core learning experience is also well-aligned with Papert's constructionism (Papert and Harel, 1991), which posits that learning is "building relationships between old and new knowledge, in interactions with others, while creating artifacts of social relevance" (Kafai, 2006, p. 35).

DBE also aligns with the theories of collaborative learning. Collaboration and social interactions are particularly relevant to design, as design in the real world often involves multiple stakeholders and experts. For instance, designing a smartphone requires collaboration between user experience designers, mobile application programmers, hardware engineers, and other stakeholders. DBE is built upon diverse approaches of collaboration, such as knowledge co-construction (Borge et al., 2020), negotiations (Jung et al., 2017), and peer supports (Melander Bowden, 2019) to empower people to learn with and from each other.

In addition, project-based learning and problem-based learning are connected with DBE. Project-based learning supports learners to be situated in their authentic projects, through which they can apply ideas and solve authentic problems (Krajcik and Shin, 2014). Similar to project-based learning, problem-based learning enables learners to be active agents who analyze and solve ill-structured and complex problems (Lu et al., 2014). The features of DBE overlap with both approaches because they are centered on learning-by-doing and inquiry-based procedure. DBE differs from either approach as it focuses on creating a product (either tangible or intangible), and iterative, numerous problem-solving occur during the design process. Acknowledging these commonalities and features of DBE, Barak and Assal (2018) developed the P3 framework combining practice, problem-solving, and project-based learning to support STEM DBE with designing robotics. Building upon these studies, as shown in Fig. 1, our framework illustrates that research and practice of DBE are at the nexus of various perspectives and theories on learning.

Rationale of design-based education: for the 21st century

The 21st century education is distinct in many ways from the traditional (20th century) education; it focuses on learner-centered pedagogy, critical thinking, collaboration, interest-driven learning, and interdisciplinarity (Thomas and Brown, 2011). The practical and theoretical foundations of DBE align well with these foci.

One of the main characteristics of the 21st century education is its emphasis on learner-centeredness (Thomas and Brown, 2011). The 21st century education centers around learners' active roles that entail what and how they think and do, which is different from instruction-based education that focuses on delivering content knowledge and positions learners as passive receivers. Hands-on design experiences, through which learners become creators, have been integrated in the form of project-based learning or constructive learning to facilitate learner-oriented activities in STEM education (Dym et al., 2005; Keune et al., 2015; Kim and Zimmerman, 2019).

The 21st century education also emphasizes higher-order cognitive skills such as critical thinking and scientific reasoning, which have been highlighted to be important skills for STEM learning. As learners apply these higher-order cognitive skills in the design process (e.g., analyze, plan, assess), DBE for STEM education can help learners develop essential 21st century skills (Razzouk and Shute, 2012). Furthermore, DBE can bridge between real-life cases and what they learn in classrooms (or other educational settings) (Koh et al., 2015) by situating learners within authentic STEM problems and providing a learning space to apply and train higher-order cognitive skills.

Moreover, collaborative skills, which is another important competence for the 21st century learners, can be empowered through DBE (Koh et al., 2015). The design process involves analyzing and coordinating diverse perspectives and solutions that may come

from different stakeholders, and this requires effective communication as well as collaboration. Similarly, for many professions in STEM fields, the ability to communicate and collaborate are essential skills for success. This means that DBE can help learners improve communication skills and help them practice collaborative problem-solving with other learners.

In addition to cognitive skills and competencies, DBE can also support emotional and affective aspects (e.g., interest and agency) of STEM learning. Developing interest and supporting interest-driven learning have been recognized as a key strategy for the 21st century education because interest can lead to deeper and voluntary engagement (Ito et al., 2013). Also, hands-on designing experiences have been shown to maintain learners' interest and develop epistemic agency (Jung et al., 2020). Therefore, DBE can support both cognitive and emotional growth in STEM of the 21st century learners.

Lastly, unlike the traditional education that was strict with the boundaries between disciplines, the 21st century education has focused on crossing diverse disciplines (i.e., inter- and multi-disciplinarity). Such shift led to emphasis on learners' ability to integrate knowledge from diverse areas. This is particularly true for STEM education because design process entails incorporating diverse perspectives that are derived from different people and fields. Therefore, DBE can bridge across the disciplines of science, technology, engineering, and mathematics for the integrative STEM education (Donna, 2012; Li et al., 2019).

Current applications of design-based education in STEM

Design-based education (DBE) has been applied to diverse educational settings in and out of schools across K-16, parallel to innovative movements in STEM education. In this article, we focus on the application of DBE in three educational settings: (a) engineering design and maker education, (b) computational thinking and STEM+C (computer science) education, and (c) digital literacy and new media creation. While we divide educational settings into three categories for the purpose of reviewing, we state that these categories are not mutually exclusive from each other. Rather, they overlap with one another because of the interdisciplinary and connective nature of DBE.

DBE with engineering design and maker education

Among different fields within STEM, engineering has been historically known to incorporate design thinking approach and design processes at their core. Accordingly, DBE for STEM has utilized the pedagogical approach of engineering design and making. Engineering design is a process practiced by engineers to identify and solve real-world problems. A framework for K-12 science education in USA (National Research Council, 2012) lists the following practices as part of engineering design process: (1) defining problems, (2) developing and using models, (3) planning and carrying out investigations, (4) analyzing and interpreting data, (5) using mathematics and computational thinking, (6) designing solutions, (7) engaging in argument from evidence, and (8) obtaining, evaluating, and communicating information. While engineering design continues to be integrated in STEM curricula within formal settings (Lachapelle and Cunningham, 2019; Moore et al., 2014), "making" has gained attention from educators within out-of-school environments as a way to support STEM learning in personally-relevant, playful ways with the rise of the Maker Movement.

The Maker Movement can be defined as participation in a community of practice that promotes creative production in art, science, and engineering with the use of digital and physical technologies in physical and/or virtual settings (Dougherty, 2012; Sheridan et al., 2014). With its origin in DIY and hacker culture, the Maker Movement is characterized by open exploration that values collaboration and distributed expertise. Research has shown that making can be one of the ways to engage learners to imagine STEM-related identity and future trajectories (Vossoughi and Bevan, 2014) as learners move toward full participation in the socio-cultural practices of the maker community. While comprehensive reviews of literature and best practices of the Maker Movement can provide more holistic overview of the learning outcomes (e.g., Association of Science-Technology Centers and Urban Libraries Council, 2014; Vossoughi and Bevan, 2014; Whyte, 2016), we particularly interpret it as part of the DBE pedagogy and present examples from K-12, out-of-school, and higher-education settings.

K-12 settings

The promising results of the makerspaces has led formal learning institutions to adopt them. An example of early efforts that introduced engineering design and making to formal STEM education settings is the development of FabLearn Labs. FabLearn Labs provides digital fabrication and high-tech equipment for construction to K-12 schools and university partners in 24 countries across six countries (Blikstein and Krannich, 2013). A case study of two FabLearn Labs in middle schools illustrated that problem-based learning approach in digital fabrication makerspaces, when positioned as part of the core curriculum rather than electives, provided a huge educational potential (Chan and Blikstein, 2018). However, the study also highlighted that self-directed and inquiry-driven STEM learning was dependent upon vigilant teaching and facilitation and carefully crafted design challenges and pedagogy.

When the provision of high-tech materials and a designated makerspace is not viable, public schools promote the tinkering disposition through creating design challenges that align with project-based learning principles. Purdue Polytechnique High School located in downtown Indianapolis is an example of how maker ethos is nurtured within the entire curriculum (Purdue University, 2019). It is a free public charter school that encourages project-based learning, in which students team up to develop a solution for real-world challenges that are initiated by industry partners and experts. Their curriculum follows the five-step iterative design process that are similar to engineering design process: initiate (discovering the challenge), empathize (understand users' needs),

analyze (define and ideate), execute (prototype and implement solutions), and reflect. Some of their design challenge examples are from conservation efforts in partnership with diverse community partners: how to enhance fan and player experience on the rink and ticket booth in partnership with Indy Fuel Hockey or how to improve transportation network in Indianapolis in collaboration with IndyGo.

The inclusion of engineering experiences in STEM curricula is also underway through developing frameworks (Moore et al., 2014), articulating the engineering practices in education (Cunningham and Kelly, 2017), and documenting how engineering design approaches help to contextualize mathematics and science principles while enhancing motivation and STEM interest to solve complex, real-world problems (Barrett et al., 2014; Bowker, 2007). These curricula activities, for example, asked students to design, construct, test, and evaluate a trebuchet catapult, a 3D model of a paper airplane that would be airborne for as long as possible, and a wind tunnel by considering basic tornado mechanics and structural engineering principles. In addition, public schools have been taking initiatives to use school librarians or media specialists to work closely with science teachers to develop design-based STEM curricula (Philips et al., 2018).

Out-of-school settings

Emerging research of makerspaces and making programs in out-of-school settings demonstrates that making can instill learners' STEM interest and position learners to pursue future STEM activities and identity. For instance, the Exploratorium created an after-school tinkering program—in partnership with Lighthouse community charter school, the University of Washington, and the Boys and Girls club—to expand tinkering dispositions beyond one-time visit to an informal learning institution and develop interdisciplinary forms of STEM learning. Their curricula included designing and making scribble machines, stop-motion animation films, shadow plays, wooden pinball machines, and musical instruments, which focused on connecting the scientific concepts with personal interests and cultural histories to support meaning-making, while promoting practices of iterative problem-solving and play. Making a scribbling machine, for example, utilized markers, craft materials, and battery-powered motors to move and create scribbling lines, thus it required learners' engagement with various STEM concepts such as circuitry, vibration, kinetic motion, and symmetry. This tinkering activity supported learners to experiment with different materials, change different parameters within the design (i.e., place a material to a different position), and engage in engineering practices through the iterative cycles of trial-and-error. As such, the afterschool tinkering program supported learners, particularly those who might be positioned as less successful according to the school standards, to make connections to ideas and practices from home or school into the afterschool setting and vice versa (Vossoughi et al., 2013).

In rural communities in which permanent makerspaces are not a viable option, pop-up makerspaces or making programs are being introduced to share the STEM resources and expertise with underserved and marginalized populations. For example, mobile makerspaces (Moorefield-Lang, 2015), circulation making kits (Simpson and Maltese, 2019), and pop-up STEM programs (Kim and Zimmerman, 2019; Philips et al., 2018) underscored engineering design process in the making activities. Also, the Chicago Public library opened Mini MakerLabs, utilizing a van to take equipment such as 3D printers, laser cutters, milling machine, to provide resources for learners from marginalized populations to engage in engineering design.

Higher education settings

Similarly, higher education settings have been increasingly implementing makerspaces to support academic, extracurricular, and personally-driven projects for university students, faculty, and staff. Many of the makerspaces are either located within engineering-related departments—to address particular needs for engineering students—or university libraries—to help non-engineering students apply engineering design thinking and process. The rise of academic makerspaces has accelerated the culture of promoting engineering design. While approaches differ, a common theme in academic makerspaces is to provide a space to develop skills to design, manufacture, test, and improve solutions to real-world problems (Wilczynski, 2015). Recently, efforts have taken place to connect hands-on making activities into university curriculum across different disciplines to cultivate the culture of innovation and creativity. For instance, the University of Texas at Arlington—in partnership with University of Nevada-Reno—implemented cross-disciplinary maker-based competencies into multiple undergraduate curricula (i.e., art, biology, education, mathematics). The project created newly adapted assignments that incorporated making into the undergraduate curriculum, while still addressing the desired course learning outcomes (Wallace et al., 2017). As such, academic makerspaces contribute to expanding the design-centered approach of engineering design to university students, faculty, and staff who are less familiar with engineering, design, and making.

DBE with computational thinking and STEM+C

Computational thinking is another skill set that can benefit from DBE. With growing interests toward the role of information technology in society, computational thinking has become one of the key agendas in the realm of STEM education. Of varying components of design, computational thinking is a critical one in fostering problem-solving skills (Brooks and Sjöberg, 2020; Wu et al., 2019) that are required for the 21st century education. Despite various definitions of computational thinking, we use Rode et al.'s list of characteristics (2015, p. 240) that was adapted from Barr and Stephenson's (2011):

- Analyzing and organizing data logically
- Visualizing data through abstractions, modeling, and simulations

- Formulating problems in a way a computer can help in solving them
- Identifying, analyzing, and implementing solutions effectively and efficiently
- Using algorithmic thinking to automate solutions
- Generalizing and applying this problem-solving process to other kinds of problems

The examples of DBE with computational thinking are derived from STEM and/or STEM+C (STEM+Computer Science) education settings where learners engage with design process to address interdisciplinary, STEM-related problems by utilizing and developing computational thinking. Learners in these settings are supported to design games, robotics, and/or coding (programming) by using computers and other technological tools.

K-12 settings (both school and out-of-school)

DBE with computational thinking has been explored extensively in K-12 STEM education settings both in and outside of classrooms. Due to computational thinking's close link with programming and electrical circuitry, most of the DBE activities revolve around engaging learners to perform fun computational projects. Oftentimes, these projects involve block/visual programming, game design, and maker projects with small hardware. For instance, [Rode et al. \(2015\)](#) conducted participatory action research about how children in a computer club at a German primary school demonstrated skill sets related to computational thinking during their engagement with e-textiles and the LilyPad Arduino. Children participated in two activities: *Bunny Bright* and *Monster Making*. During the first activity, children used circuit board, LED lights, and textiles to become familiar with basic electrical concepts. The second activity integrated block programming component. The study illustrated that children were able to engage in computational skill sets and practice new core skills such as *aesthetics, creativity, constructing, visualizing multiple representations, and understanding materials* (p. 241), which are closely related to computational making and design thinking. Through their study, they asserted the importance of expanding the notion of computational thinking to computational making because computing has extended beyond desktop usage. Similarly, [Richard and Giri \(2019\)](#) observed an elective mini-course on making at a public magnet high school where students engaged in bidirectional design activities by using between digital and physical design kits. During the workshop, students built models through collaborative projects with digital and tangible maker toolkits, such as Makey Makey, LilyPad Arduino, ModKit, and Scratch. Through multimodal analysis of the students' activities, the researchers found evidence for different practices of computational thinking among learners, designing circuits, coding, and understanding complex systems. [Mel-ander Bowden \(2019\)](#) used Scratch to engage students in problem solving through game design activity. During the activity, students were prompted to redesign a Scratch game by modifying visual and auditory components. The author focused on exploring the social nature of problem solving throughout design process. [Kynigos and Grizioti \(2020\)](#) saw game modding as an effective tool for developing computational thinking skills.

DBE with computational thinking has also addressed the needs of learners in out-of-school settings. [Brooks and Sjöberg \(2020\)](#) explored elementary-aged children in creative workshops where children in groups designed games using creative materials and digital technology. They were asked to create a short stop-motion film for their game design prototype. Through the interaction analysis and quasi-content analysis approaches, the authors discovered that children developed specific kinds of computational skills such as step-by-step procedural skills, design and arrangement skills, and computational perspectives (p. 93). The authors concluded that reverse engineering approach that involve the designerly activity can help learners understand computational thinking skills. [Wagh et al. \(2017\)](#) reported on an ethnographic study involving a group of high school students working on a project in a paid summer program, the Youth Maker-Teacher Program. The group of students worked on a project called WaterWorks project, which was described as "a musical water fountain that changes color when different Jumbo piano keys are pressed" (p. 3). By analyzing video and audio recordings, field notes, photographs, artifacts, and group's blog posts, the researchers discovered that the group mainly practiced problem decomposition and simulation as well as troubleshooting and debugging. Both studies involved workshop activities where students would work on design activities as a group. They would participate in problem solving activities, which, in turn, could facilitate computational thinking practices.

Higher education settings

Game-related activities have been found to be useful in higher education settings as well. Interests toward computational thinking have been expanded to not only STEM majors but also diverse disciplines. For instance, [Marcelino et al. \(2018\)](#) used Scratch to train elementary school teachers in distance higher-education settings to engage them in computational thinking related activities. The trainees went through computational thinking-related themes with various activities and completed a final project during the course. During the course, the trainees learned about computational thinking concepts, explored the usage of Scratch in school settings, learned to program and build an application using Scratch. To teach introductory programming within the STEM discipline, [Kazimoglu et al. \(2012\)](#) used game prototype and helped students develop computational thinking skills that were expressed through practices, such as problem solving, building algorithms debugging, simulation, and socializing.

DBE with digital literacy and new media creation

Digital literacy (i.e., media literacy, multimedia literacy) is the ability to understand, manipulate, transform, and distribute digital media ([Burdick and Willis, 2011](#)). Digital literacy is critical in the 21st century education because such ability of utilizing digital

media and resources can impact learning performances and outcomes (Banerjee and Gibbs, 2016; Lemke et al., 2014). In other words, digital literacy is the core competence to understand, collect, analyze, and create information in any discipline of STEM. As a result, it is gaining more attention as a bridge to connect different educational practices from multiple STEM disciplines. Studies have also shown that digital literacy matters to learners' STEM-related interests and future careers (Bekker et al., 2015). Thus, understanding and promoting digital literacy could enhance the quality of integrative STEM education.

New media creation, which is tightly related to digital literacy, is another area of design. In addition to tangible and physical products, creating web-based or hybrid digital media also requires design thinking and process. DBE with new media can include a wide range of creative production, including digital storytelling using videos, websites, or blogs (e.g., Chan et al., 2017; Hill and Grinnell, 2015; Rahm and Moore, 2015) and creative visualization utilizing digital media and data (e.g., Stornaiuolo, 2020). New media creation needs skills for research, problem-solving, assessing, technology, interpretation, and reflection, which are all critical for STEM learning (Chan et al., 2017; Hill and Grinnell, 2015). In this section, we review the cases of DBE with (and for) digital literacy and/or new media creation in STEM education settings.

K-12 settings (both school and out-of-school)

DBE with multimedia design has been integrated into diverse curricula and educational activities in K-12 settings. Liu (2003) designed a three-phase curriculum called Learner-As-Multimedia-Designer, through which students in elementary, middle, and high schools designed multimedia products. In the first phase, students learned about required tools for media creation (e.g., software and hardware), in the second phase, students designed products for clients (e.g., a multimedia presentation for teachers' job fair) through planning, designing, producing, and evaluating and revising, and lastly in the third phase, they repeated the cycle of the second phase for another project. Groups of students collaborated on attaining graphics, creating digital video and audio clips and animations, and merging the digital resources for their final media product. This multimedia design activity was shown to enhance the students' cognitive and collaborative skills.

Diverse DBE programs with new media were implemented in out-of-school settings as well. In a weekly afterschool club from Rahm's study (2016), nine high school students participated in video production activities over 12 weeks. The DBE activities included brainstorming, fieldtrips to community science centers (e.g., botanical garden), topic development for collaborative video production, as well as storyboard making, filming, and editing videos. Students took the photos and videos by themselves from the fieldtrip and utilized them as sources of their video design. Another notable example is YOUMedia. YOUMedia supported interest-driven and collaborative learning through digital media creation across diverse environments, including libraries, museums, and afterschool clubs (Ito et al., 2013). YOUMedia's programs utilized digital media creation to hang out, mess around, and geek out on areas related to STEM (e.g., electronic gaming, design) and the arts (e.g., music, writing). Teenagers in this program chose their own interest, by communicating with their mentors and peers in person as well as through social media (e.g., iRemix), and participated in a range of design projects with new media. They were encouraged to design and create new media production about their own interests, such as podcasts, blog posts, and journal articles, while their content knowledge and digital literacy were also empowered.

To enhance digital literacy, some incorporated both digital and physical technology into learners' design activities. In Stornaiuolo's study (2020), students in a media makerspace at a public high school learned how to interpret and analyze web-based data using Google Trends and DataBasic web tools. This DBE curriculum focused on digital literacy related to data (i.e., data literacy). Students in this curriculum collected personal data and designed their own visualization of their data story, with which they created a key and printed onto T-shirts. Through designing their own visualization with data and data stories, students learned how to understand and use data in creative ways. They also developed agency in terms of utilizing digital resources and data. Bekker et al. (2015) also focused on enhancing digital literacy of elementary and secondary school students by utilizing digital and tangible toolkits for their design-based learning efforts. Students were asked to design innovative products, such as new interactive and sustainable lamp. For their design projects, students followed the steps of imagine/discover, make/prototype, test/present, and reflect, which are essential components of DBE. Throughout their design processes, students were able to engage with STEM-related contents as well as enhance digital literacy.

Higher education settings

DBE with new media creation, especially in a format of digital storytelling, has been widely used in higher education contexts. Hill and Grinnell (2015) adopted digital storytelling with infographics for STEM major students. Students were asked to create "story resumes"—a form of digital resume through storytelling—including infographics as well as videos. They created movies using their smartphones, PowerPoint, as well as sound and video functions. By designing their story resumes, these students were able to reflect on their competencies and attained digital literacy skills to create the infographics and videos. In a course about technology at a community college in Hong Kong, Chan et al. (2017) employed digital storytelling to enhance students' deep learning. Students designed their own storytelling videos through brainstorming, planning and storyboard sketching, and filming and producing videos about the themes of their choice. While this process improved the students' skills and competence related to digital literacy as they had to learn about multimedia concepts, they also developed skill sets for design by using software for video editing (e.g., Adobe Premiere Pro) and hardware devices (e.g., video cameras and microphones) to create their storytelling videos. This process also helped them deeply engage with the concept knowledge of their choice. The d.School from the Stanford Hasso Plattner

Institute of Design is another example that employed design thinking in higher education, especially across diverse disciplines within and beyond STEM. Professors from different departments taught courses together, and students could enhance design thinking through interdisciplinary opportunities and projects. To pursue innovation, d.school emphasized enhancing students' ability to use and leverage technology and knowledge (Banerjee and Gibbs, 2016). In other words, digital literacy, as well as design process, acted as the core ability and the bridge across various disciplines.

Interdisciplinarity of the current applications

Although we divide the study cases into STEM (engineering design and maker education, computational thinking and STEM+C education, and digital literacy and digital media creation) categories, some of the examples fall into all three categories. For instance, Bekker et al. (2015) DBE program focused on enhancing digital literacy but through designing activities with both digital and physical toolkits, and these are also tightly related with maker education and computational thinking. Also, d.school represents a large-scale educational effort that supported diverse types of innovative thinking and behaviors rooted from interdisciplinary knowledge. As such, DBE has potential to support digital literacy engineering thinking, maker activities, computational thinking, as well as conceptual learning in STEM, on the basis of design thinking and process.

Designing design-based education for STEM learning: principles and gaps

How to design learner experience in design-based education (DBE) in STEM is a critical question for researchers and practitioners to better serve learners, especially because DBE entails complex problem-solving and higher-order cognitive activities. Puntambekar and Kolodner (2005) employed distributed scaffolding to support middle school students' design-based learning activities that are related to a scientific phenomenon, erosion. The authors implemented principles of scaffolding for DBE: (a) creating common goals, (b) providing ongoing diagnosis, (c) providing dynamic and adaptive support, (d) including dialogs and interactions, and (e) positing fading and transfer of responsibility. In particular, they emphasized "understanding of the processes involved in learning science by design and what [educators] knew about student difficulties" (p. 190). In other words, rather than product-oriented assessments and facilitation, process-oriented supports are essential for better learning experiences in DBE.

However, training teachers, as well as informal educators and parents, to become facilitators of DBE is still a remaining task for the future of DBE. The cases we reviewed barely demonstrated how teachers were trained to design and implement DBE. Moreover, some studies (e.g., Chan and Blikstein, 2018; Lee et al., 2017) even discussed the necessity of proper preparation for this new teaching method. DBE requires immense efforts of educators to accommodate differentiated needs depending on different designs. Without proper training, educators and parents in DBE may impose learners on pre-determined answers despite the fact that it is important to support learners' own tinkering and making throughout the design process (Jung et al., 2020). Therefore, we point out the necessity to come up with systemic and concrete plans for supporting educators to empower learners in DBE and better design DBE activities for STEM learning.

We also identify the gap between the interdisciplinarity that many DBE programs pursued and the integrative STEM education. Despite the meaningful insights of DBE from current examples, we barely found the examples of DBE that explicitly connect with mathematics education among STEM areas. In fact, most of them were related to technology and engineering. Although DBE ideally pursues various, individual disciplines in STEM as well as integrative STEM education (Donna, 2012; Li et al., 2019), current DBE practices only allowed limited integration of STEM disciplines. For integrative STEM education, establishing intentional connections among concepts and practices of S, T, E, and M disciplines is essential (Sanders, 2012). Therefore, efforts to make precise, clear, and explicit connections between each of the STEM areas is another remaining task when planning and implementing DBE in STEM.

Conclusion

In this article, we conceptualize design-based education (DBE) in STEM educational settings by overviewing related theories, including socio-constructive and sociocultural perspectives, constructionism, project-based and problem-based learning, and collaborative learning. We also introduce the rationale and benefits of DBE, especially for the 21st century education. We also review the current examples of DBE practices, which provide insights for what types of DBE exist and how researchers can apply DBE to certain STEM education settings. While our review of the DBE practices categorized three innovative STEM education movements (engineering design and maker education, computational thinking and STEM+C education, and digital literacy and digital media creation), we also highlight the potential of DBE in connecting all of these categories. If the lack of explicit efforts for integrative STEM education and the systemic supports for training educators can be addressed, the future DBE will better support children and youths to grow as critical and creative leaders for the 21st century.

Introduction

Collaborative learning is an ancient wisdom. In one of the Confucian classics *Li Ji* (礼记), there is a famous saying—“one becomes narrow-minded if learning without peers.” In contrast to individual learning, collaborative learning provides learners with the opportunity to interact with others, and hence, increase their opportunities to learn.

Many complex problems in the science, technology, engineering, and mathematics (STEM) fields such as climate change and infectious disease control require collaborative problem solving. For example, to fight against the new corona virus pandemic, policy makers need to work with different sectors—including scientists, health care workers, and the media—to make and implement effective policies and strategies. It is necessary to prepare younger generations with a collaborative mindset to be able to tackle real life problems and challenges.

There is also an increasing demand of new forms of collaboration due to the widespread application of modern digital tools and social-network platforms. Consider some of the common scenarios today in- and out-of-school environments: a small team works in an online chat room to solve a math problem together; a class is using a discussion board asynchronously to brainstorm ideas on a science topic; a community of game players discuss mechanisms to solve embedded technical bugs. To reflect the trend of integrating technologies in education, this article focuses on Technology-Enhanced Collaborative Learning (TECL) in STEM.

Parameters and forces of collaborative learning

In this article, we adopt the broad definition of collaborative learning by [Dillenbourg \(1999\)](#): “a situation in which two or more people learn or attempt to learn something together” (p. 1). In theory, collaborative learning is built upon social constructivism ([Adams, 2006](#)), which submits that learning happens during the process of social interaction ([Vygotsky, 1978](#)). In practice, the key to defining a specific form of collaborative learning is through specifying its various pragmatic parameters: The scale of collaborative learning can be as small as a pair on one end, and as big as a large community on the other; the timing can vary, such as in a year-long course, or in a one-shot activity (e.g., a team-building activity at a firm); the setting can change from physical collaborative learning to virtual ones; the medium may include various technological platforms, and so forth.

Besides these pragmatic parameters, the dynamics of collaborative learning are shaped by different forces at play. One such force is the preference to individualism or collectivism in terms of the learning objective. If the learning objective is set for the individual, collaborative learning will foreground the improvement of individual knowledge or skills. For instance, to assess students’ collaborative problem-solving competency in the PISA test, [OECD \(2017, p. 6\)](#) defined it as “the capacity of an individual to effectively engage in a process whereby two or more agents attempt to solve a problem by sharing the understanding and effort required to come to a solution and pooling their knowledge, skills and efforts to reach that solution.”

Alternatively, when the learning objective is for the collective, community building and collective knowledge construction are prioritized. For example, the notion “team-based learning” focuses on small-group interaction in a class setting and requires that assignments promote team development in addition to individual learning ([Michaelsen, 1992](#); [Michaelsen and Sweet, 2008](#)). In a similar vein, those who advocate “communities of practice” ([Wenger, 2011](#)) or Knowledge Building ([Scardamalia and Bereiter,](#)

2006, 2014) emphasize the importance of building a community for learners. Communities of practice are “groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly” (Wenger, 2011, p. 1). The Knowledge Building theory stresses more on the creation and innovation of collective knowledge, and prioritizes community knowledge advancement instead of individual accomplishment (Scardamalia and Bereiter, 2006).

Another force that influences collaborative learning is division of labor. In many learning occasions labor division is set clearly by instructors or supervisors (i.e., the work is divided into independent sub-tasks and then the group assembles different parts together; Nugraha et al., 2019). “Cooperative learning” (Johnson and Johnson, 1994) is often used in these cases. In other collaborative learning occasions, work is not split, but negotiated and completed jointly by the individuals involved (Micari and Pazos, 2020).

Often conceived as resistance to collaboration, competition refers to the action that two or more parties battle for a common benefit or recognition that cannot be shared. In the collaborative learning environment, all group members contribute to the same learning task. In contrast, in a competitive environment, learners work independently and try to outperform others. However, collaboration and competition are not necessarily incompatible to each other. Contradiction may serve as a driving force in advancing an activity system (Roth et al., 2004). Likewise, competition may serve as a positive ingredient to collaborative learning (Mayer, 2009; Ziegler and Hamker, 2011). It is often coexisting with collaboration within or across group learning settings (Shen et al., 2020a). Therefore, a competitive mindset could be a double-edged sword: When carefully scaffolded and well-harnessed, it can facilitate the collaborative problem-solving process; if not, competition may undermine collaboration.

Benefits of collaborative learning in STEM education

Collaborative learning has been well embraced in STEM education (see a systematic literature review by Thibaut et al., 2018). Building student learning communities is recommended as a strategy to increase students’ interest and persistence in college STEM programs (Sithole et al., 2017). Several meta-analysis studies have demonstrated that collaborative learning promotes student learning in general (Chen et al., 2018; Kyndt et al., 2013; Roseth et al., 2008). Moreover, according to a more recent meta-analysis, computer-supported collaborative learning has shown notable effectiveness in STEM education, including the process, knowledge, and affective outcomes (Jeong et al., 2019).

More importantly, research has shown strong evidence that collaborative learning is contributing to addressing critical issues in STEM education (Laal and Ghodsi, 2012; Panitz, 1999). One such issue is low enrollment and high attrition (Chen and Soldner, 2013; HESA, 2021; Lichtenberger and George-Jackson, 2013; Romash, 2019; Sithole et al., 2017). Collaborative learning may enhance students’ self-esteem and sense of achievement by, e.g., allowing them to help others and having them involved in the design of class activities (Johnson and Johnson, 1990). Students can develop more higher-order thinking skills and learn better on STEM content as a result of collaborative learning than individual learning (Gokhale, 1995; Johnson and Johnson, 2009; Webb, 1982). Collaborative learning may also foster students’ communication skills and abilities to resolve conflict (Johnson and Johnson, 1990; Tolmie et al., 2010).

Another issue is equity in STEM education. For example, female students generally have a lower enrollment rate yet higher attrition rate in postsecondary STEM majors than male students. Likewise, students from low-income families exhibit similar patterns when compared with students from high-income families (Chen and Soldner, 2013; English, 2017; HESA, 2021; Lichtenberger and George-Jackson, 2013). Research has shown that students’ satisfaction toward the positive experience of collaborative learning makes them more intrinsically interested in learning and therefore, they become more willing to attend school and to persist in STEM learning. Additionally, collaborative learning promotes communication and interdependence among all group members, regardless of race, gender, and level of achievement, leading to a more equitable learning environment (Esmonde, 2009; Panitz, 1999).

TECL in STEM education

Technology plays an important role in facilitating collaborative learning. It may provide visual representations of learning tasks, guide collaboration processes, and serve as scaffolding to building collective knowledge (Chen et al., 2018; Goodyear et al., 2014). In the following, we focus on examples of technologies that directly support collaboration during the learning process. Some technologies may be used for collaborative learning, but do not play a central role in collaboration. For example, Lee et al. (2016) documented a study in which students collected their own activity data (e.g., step counts with time) by wearing sport watches and learn statistics by exploring the data in groups. The sport watch was used for data collection, rather than to facilitate collaboration. This type of studies is beyond the scope of this article.

Connecting learners across space

Remote collaborative learning environments

Audio and video conferencing tools (e.g., Zoom, Skype) are widely used nowadays in synchronous, distance learning settings. These tools provide a mechanism to connect learners across space. Many of them have specific features that support collaborative learning such as screen sharing, chat room, and annotation. Babaian and Schiano (2020) listed several practical tips for facilitating small group work in online learning. They encouraged both instructors and students be familiar with the features that support small group

work, including managing display names and changing screen name to group ID/name, navigating between breakout rooms and the main room, sending messages to all groups or a specific group in the breakout room, and being familiar with sharing or annotation tools. Research has also been conducted to examine these features. For instance, Singhal (2020) showed how breakout rooms in Zoom could be utilized in a virtual pharmacotherapeutics course during COVID-19. In the class, every five to six students were grouped and assigned to a breakout room, and the instructor was able to move around the rooms to facilitate discussions. The author argued that using breakout room could aid students' small team assignment in promoting active learning and therefore, leading to more participation.

Multi-user virtual environments (MUEs)

Multi-user virtual environments (MUEs) have been used for facilitating collaborative learning. In these environments, learners usually take on avatars to interact with one another in a virtual world, similar to popular (massive) multiplayer online role-playing games (Barab et al., 2005). It has been found that these learning environments may bring learning benefits to students with autism spectrum conditions (e.g., Cheng and Ye, 2010).

A pioneering example in science education is River City, an MUE learning environment designed to engage middle grade students in standards-based scientific inquiry practices (<https://muve.gse.harvard.edu/>). The curriculum improved over multiple versions of development (Ketelhut et al., 2010). For instance, the very first unit focused on biology and ecology. Joining via avatars, students could investigate authentic problems (e.g., diseases in the town) in a virtual town with a river running through it. To solve the problems, students must collaborate to share information and communicate with team members on what data they have gathered via a chat-in-text tool. In retrospection, Ketelhut et al. (2010) concluded that "MUEs are viable tools allowing learner-centered, collaborative inquiry learning that can provide an alternative to more conventional kinds of inquiry-based science instruction" (p. 108).

Ibanez et al. (2013) proposed a 3D virtual collaborative learning model that guides learners' collaborative activities in MUEs. The model specifies synchronization learning points in order to achieve the desired learning objectives of individuals or groups, as well as division of labor to promote positive interdependence. Based on the model, they conducted a case study in which participants (via avatars) walking up and down a street in the 3D environment and collecting information related to available theater shows, with the goal of purchasing ticket for the show they would like to attend. The participants needed to carry out several collaborative activities including sharing information and group assessments. The researchers were able to identify factors that influenced interactive collaboration in the first iteration and improved the design that resulted better collaboration in the second one.

Different from the examples above that have game-like settings, Hwang and Hu (2013) described a unit on geometry for fifth graders in which students worked in a virtual classroom setting. In this environment, students could manipulate virtual 3D geometric objects, observe peers' problem-solving processes, and send critiques and comments to each other. Their study showed that the experiment group performed significantly better than the control group on learning geometry. According to their study, manipulating the virtual objects and collaborating with peers (e.g., observing and criticizing peers' solutions) were key processes for students to learn abstract geometry concepts (Hwang and Hu, 2013).

Note that manipulations of virtual objects could also facilitate face-to-face peer interactions. Jackson et al. (2013) developed a tabletop-based math game activity to supplement and reinforce what students had learned in the fourth-grade math class. The math problem was displayed in the center of the tabletop screen (which allows multiple users to manipulate on the screen simultaneously) and required students to fill in blanks with elements from their resource pools. Four students worked in a group and each of them controlled a resource pool that may contain necessary elements in the solution, so they must collaborate to complete the problem. Students demonstrated favor to the collaborative game learning activity and boys significantly improved their math grades after the program.

In sum, both audio/video conferencing tools and MUEs are mechanisms that connect learners across space. While audio/video conferencing tools have been used in our daily life, more empirical studies on specific features of these tools that can best facilitate collaborative learning are still needed. Unlike audio/video conferencing tools, MUEs not only provide a common, alternative space for learners, but also simulate task scenarios. Through exploring virtual environments and manipulating virtual objects, learners could experience the problem-solving process in a more authentic way.

Facilitating group written discourse

While audio or video conferencing tools makes remote communication convenient and efficient, they require high speed Internet and extra devices (i.e., camera and microphone). In comparison, written discourse can satisfy the need of collaborative learning without these constraints.

Synchronous discussion forum

A synchronous discussion forum provides the opportunity of real time interaction with written texts or symbols (Kuyath, 2008; Rosé and Ferschke, 2016). In addition to enabling communication, some advanced synchronous discussion forums for educational purposes even include virtual intelligent agents to provide in-time feedback on the contents of learners' discussion. Wang et al. (2011) conducted a study in which high school students worked in pairs on geology-related brainstorming tasks. They used VIBRANT, a synchronous chat software with an embedded virtual agent that was able to provide real-time feedback. Tegos et al. (2016) showed a similar synchronous conversational platform MentorChat with a virtual agent that facilitated dyad collaborative

learning of 96 university students on the topic of human-computer interaction. In both learning environments, the virtual agent appeared as the third person to participate in the team dialog, commenting and asking guiding questions based on their discourse texts. Both studies indicated positive effect of using the virtual agent in enhancing students' collaborative learning.

Asynchronous discussion tool/forum

Whereas synchronous discussion tools have the advantage of satisfying learner's desire of having instant interactions and feedback, asynchronous discussion tools allow learners adequate time to review peers' posts and to provide more contributive comments. In one study that investigated collaborative learning in an undergraduate engineering course, the instructor asked group members to discuss the team task through email and to turn in a group report based on the email communication (Liu et al., 2018).

A shared web-based space (e.g., blogs) can serve as an asynchronous discussion forum for viewpoint exchange. For example, Jimoyiannis and Angelaina (2012) engaged 21 middle school students in the investigation of the acid rain problem using educational blogs. All the students who participated in the blog formed a learning community. They posted their individual findings and commented on each other's blogs. The study found that students presented increased interest in the activity, demonstrated mutual social and emotional support, and enhanced knowledge construction through their interaction on the blog.

In a study that investigated learners' collaboration mechanism, a total of 25 pre-service teachers interacted through an asynchronous online whiteboard (Gressick and Derry, 2010). They worked in small groups of five to design an interdisciplinary instructional unit that integrated math and science. Any member in the group could post his/her design proposal and others could comment, suggest edits, and rate. They found although there was no initial labor division by the instructor, participants took on different responsibilities and leadership roles (e.g., seeking input, knowledge contribution, topic control) were highly distributed among team members.

Synchronous or asynchronous discussion forums have been around for quite some time, but they keep evolving with the development of new technology. In recent years, multimodal inputs such as audio or video have been incorporated in these online discourse platforms (e.g., Flipgrid; Guffy et al., 2021), and machine learning algorithms have been embedded to support the automated and customized feedback to learners (Rosé and Fersckhe, 2016).

Guiding collaborative process

The aforementioned technologies create more collaborative opportunities by connecting learners across time and space, yet collaboration among students is not always successful as a result of ineffective communication, lack of interaction, improper labor division, to name a few (Le et al., 2018). Researchers have explored the affordances of collaborative scripts in computer-based learning environments to guide collaborative processes. For example, Rummel et al. (2012) conducted a study of scripted collaborative math learning with 106 high school students. They added collaborative scripts to the Cognitive Tutor Algebra software, a computer-based tutoring system. Two students first worked independently on different problems, then joined on one computer to collaborate on the problem provided by the script, which combined the two individual problems they had previously. During their collaboration, more scripts popped up to prompt certain collaborative behaviors at specific time points (e.g., making contributions based on the independent problem-solving experience, listening to peers, and asking questions if not understanding anything). The results showed that the students in the scripted group presented higher quality of collaboration and problem solving than those in the unscripted group.

Apart from guiding collaborative behaviors, collaborative scripts have also been used for peer monitoring. Bouyias and Deme-triadis (2012) compared the effects of compulsory peer-monitoring prompts and the fading-out scaffolding scripts for collaborative argumentation activities in an undergraduate computer science course. Students used iArgue, a web-based argumentation learning environment. Thirty-four students were randomly assigned into groups of two. In the peer-monitoring groups, when student A submitted a task, his/her partner B would receive the submission along with a peer-monitoring prompt that requested student B to check whether A's argumentation followed the model or not, and if not, to point out where it should be improved. The monitoring task has to be completed before student B can proceed with his/her own work. Apart from peer-monitoring prompts, they also received consistent scaffolding scripts (e.g., guidance on argument construction). In the fading group, students received no peer-monitoring prompts but fading-out scaffolding scripts (i.e., less scaffolding after students' second post). The study found the peer-monitoring scripts significantly promoted learning outcomes while the fading-out scaffolding scripts did not.

In another study that investigated the function of collaborative scripts in argumentative learning, the collaborative scripts not only served as peer-monitoring prompts, but also guided the learner to systematically analyze his/her partner's argumentation and foster his/her own argumentative construction—to paraphrase, criticize, ask questions, give counterarguments, and propose new arguments (Noroozi et al., 2013). Sixty university students participated in the study and collaborated in pairs on tasks that involved both of their disciplinary backgrounds; each pair of students consisted of one from water management and the other from international development studies. The study showed that the scripts were effective in facilitating argumentative knowledge construction (Noroozi et al., 2013).

These findings suggest that collaborative scripts may guide and improve collaborative processes through prompting collaborative behaviors, providing peer monitoring, and facilitating knowledge construction, especially for small-group collaboration. Therefore, we call for more integration of collaborative scripts into teaching practices and more research on strategies to facilitate the collaboration within larger groups.

Generate, deposit, and visualize collective knowledge

Apart from increasing collaborative opportunities and guiding collaborative processes, technological tools or platforms have also been developed to facilitate collective knowledge construction and sharing. After twenty years of development, Wikipedia, an online encyclopedia, now has a repertoire of more than 56 million articles in more than 300 different language versions (https://en.wikipedia.org/wiki/List_of_Wikipedias). It has become one of the most visited websites. The idea that anyone can contribute to the most comprehensive encyclopedia, representing the state of the art of collective human knowledge, has thrived.

Wikipedia or technologies alike have been applied in classrooms at different levels. For instance, Pifarré and Kleine Staarman (2011) examined the collaborative processes of primary students working together to create a science text in a wiki environment. Using a dialogic perspective that attends to, the researchers examined student-generated texts in terms of the number of paragraphs, the number of words, the number of sentences, and the number of reasoning connectors. They concluded that a dialogic approach should be used to analyze the collaborative interaction processes and can be used to help design more effective pedagogies related to the use of wikis in classrooms. At the college level, WIKled Biology is a National Science Foundation funded project in which the researchers developed and implemented a student-centered inquiry learning model for biology classes (Frisch et al., 2013). In the project, students used Web2.0 tools to collaborate with each other, managed and tagged learning materials found on the Internet, and worked in small groups to design and publish website pages based on their scientific inquiry projects. Results showed that the students increased their understanding of certain biology topics, critical thinking skills, as well as the significance of scientific communication.

Like Wikipedia, citizen science can be considered as crowdsourcing science activities to the general public. Citizen science refers to the practice of science endeavor (e.g., data collection) by nonprofessional scientists that contributes to generating professional scientific knowledge (Bonney, 1996). For example, Digital Earth is an effort where people help collect and convert information related to Earth into its digital forms (Brovelli et al., 2020). One example of Digital Earth is OpenStreetMap (www.openstreetmap.org), a collaboration effort to create free, editable map of the world infused with geographic data collected by individual users. Its college student article, YouthMapper (www.youthmappers.org), is a global network of students who actively engage in collaborative mapping using OpenStreetMap. Coetzee et al. (2018) examined student collaborative mapping experiences in three universities in Europe, North America, and Africa. They found that these mapathon (i.e., marathon of mapping) activities could enhance students' learning not only in technical skills and subject matter knowledge, but also in terms of becoming socially engaged citizens.

A pioneer platform of collective knowledge building in K12 classrooms is Knowledge Forum, led by Marlene Scardamalia and Carl Bereiter over three decades of research and development (Scardamalia and Bereiter, 2014). Knowledge Forum is used to help and support knowledge building communities. Students create knowledge notes related to a specific topic. These posts can be organized and connected into different layers and form a part of "World 3—the body of human knowledge expressed in its manifold forms" (Chen and Hong, 2016, p. 269). One strength of Knowledge Forum is the many scaffoldings provided for students to generate their entries. For instance, prescribed prompts such as "My Theory", "My Problem of Understanding" can be selected to start a statement; rise-above notes can be added to provide high-order overviews. Key to these supports is that they are informed by and reinforce the Knowledge Building design principles. Abundant empirical research has shown that students benefit from using Knowledge Forum in improving their basic, domain-specific, and epistemic literacies (Chen and Hong, 2016).

The iKOS platform, a web-based knowledge organization platform, has been developed to facilitate interdisciplinary, collaborative learning in a classroom setting (Namdar and Shen, 2016). The platform allows users to construct, share, and organize knowledge and has the advantage of embedding multimodal elements (Jiang et al., 2019; Shen et al., 2020b). It supports multiple modes of knowledge representation: In the Wiki mode, users can create knowledge entries similar to Wikipedia; In the PicTag mode, users can tag and annotate pictures or photos; In the Concept Map mode, users can construct concept maps to visualize the connections among big ideas; In the Flipbook mode, users can publish their multimodal pages and interactive flipbooks to the general public. Research has shown that preservice science teachers are able to generate a relatively dense knowledge network after taking a unit on nuclear energy (Namdar and Shen, 2018).

Another type of tools we would like to mention is personal response systems (e.g., clickers) or polling apps (e.g., Top Hat). These tools typically go well with the instructional practice called Peer Instruction (Crouch and Mazur, 2001)—a pedagogy developed to engage students in discussion in typically lecture-based classes. A key process is to project and visualize the distribution of students' answers and responses on the screen using the clicker or the polling app. This projection of the status of the collective knowledge of a class drives and engages students in discussing with their neighbors about their choices or reasoning. This method has shown success in improving college students' learning and retention in STEM fields (Deslauriers et al., 2011; Watkins and Mazur, 2013).

The aforementioned platforms provide the space for learners from a large community to deposit, construct, and share collective knowledge. From contributing to the final product of collective knowledge, learners may not only advance community and knowledge building, but also benefit in their individual knowledge construction and other personal skills in the process.

Assess and analyze TECL in STEM

Despite the popularity, relatively little empirical work has been done in the area of assessment of TECL. One may approach assessment of collaborative learning from two aspects: collaborative products and processes. The former refers to what a collaborative group generates during the learning process, i.e., the group-level knowledge/artifacts or group performance of a learning task. These

collective outcomes can be examined to infer the collaboration processes or the team members' collaboration knowledge. The latter focuses on the messy dynamics (e.g., social interactions among group members) that bridge the individual and the collective.

For products, researchers have exploited the discourse or artifacts logged within the technological platforms during collaborative learning. For example, a synchronous or asynchronous discussion forum may record the discourses among members of the learning community, providing rich data source for assessing and analyzing their collaboration as well as knowledge construction. Jimoyianis and Angelaina (2012) conducted Community of Inquiry (CoI) analysis and Social Network Analysis (SNA) on the total 131 blog publications about the acid rain problem. Through CoI analysis, they explored the community characteristics by categorizing the publications into social presence (i.e., involving no domain knowledge but for emotional communication and group cohesion), cognitive presence (i.e., involving domain knowledge), and teacher presence (i.e., including instructions or scaffolding). Their SNA analysis quantified individual participation and the social relations among the individuals. For instance, the number of direct connections each individual had with others may indicate power distribution among students.

For processes, utilizing external tools such as video/audio recording is a common strategy to investigate collaboration processes. For example, Birchfield and Megowan-Romanowicz (2009) examined the use of a mixed-reality environment in facilitating high school students' Earth science learning. Video and audio recordings were coded based on the discourse between the students and the teacher (e.g., questions, responses) and that among students (e.g., comments, questions, or responses between individual students). The findings showed that the utterances were significantly increased in terms of student-driven exchanges.

It is common that a computer-based learning platform logs student behaviors on the platform (e.g., time stamps, clicking a button or page, edit texts). Recently, this type of log data is examined by researchers for understanding group collaborative processes. Olsen et al. (2019) conducted a study to compare how elementary students solved math problems through an online platform with a virtual intelligent tutor in different learning conditions: collaborative, individual, and combined. Researchers analyzed the log data of students' interactions with the virtual tutor—including attempts, errors, and hint requests—as an evaluation of each student's problem-solving efficiency under the assigned learning condition.

Some studies attended to both collaborative processes and products. For example, Altebarmakian and Alterman (2019) examined both the system log data and the contents of students' posts to probe 29 college students' engagement in collaboration in a course on computer science and psychology. Students collaborated on homework in small groups of 3–5 through an educational blog platform. They needed to draft and upload their independent responses to an initial problem, comment on others' posts, reply to questions raised by others, modify their own responses based on group discussions, and submit final responses. Each student's engagement in the collaboration was analyzed in terms of behavioral, social, and cognitive aspects. Behavioral engagement was measured by quantifying the student's reading, editing, and commenting behaviors logged by the system. Interactivity was based on whether or not the student referenced previous comments, which also came from the log data. Cognitive engagement was rated based on the contents of student's posts.

One observation of the assessment aspect of the collaborative learning literature is that most studies used assessments to evaluate the impact of collaboration on individual students' academic or affective outcomes. These assessments do not capture the growth of students' collaboration knowledge and/or collaborative practices. Moreover, the formative assessment during the process receives much less attention in TECL than outcome measures. When students carry out collaborative learning, it is critical to provide timely and effective feedback to individuals and groups. On-going assessment of collaborative learning enables meaningful communication between collaborative group members and between students and their teacher, resulting in a better collaborative learning experience for students. Therefore, more research is needed in the area of assessment in TECL in STEM education.

Conclusion

This article identifies the parameters, forces, and benefits of collaborative learning in STEM education. The article also provides examples of technologies that facilitate collaborative learning in different ways: connecting learners across space and time, fostering written (and multimodal) discourses among learners, guiding collaborative processes, and promoting collective knowledge. Whereas assessments of TECL have been mainly focused on collaborative products and processes to evaluate the impact of collaborative learning on (individual) students' academic and affective outcomes, formative assessment of students' collaboration knowledge and practices needs to be further explored.

Introduction

The 21st century has witnessed significant progress in science and technology, and people's lives are being dramatically changed by technological advances (Waight and Neumann, 2020). For example, more and more people are shopping online and sometimes having a better experience than with physical shopping; social media giants such as Facebook and Twitter have announced policies of permanent working from home for many of their employees, which would not be possible without highly-developed communication technology (Berliner, 2020). Nevertheless, compared to other aspects of life that science and technology have affected in profoundly revolutionary ways, education continuously remains the area that is least impacted by these advantages (Zhai et al., 2020). Partially, we argue that a reason for this dilemma is due to the very nature of education: A complex process of facilitating the acquisition of knowledge, skills, beliefs, and habits through utilizing media, communicating, and managing. It is not the technology itself, but also the roles of users, the integration of technology and learning, as well as the users' perception of technology, that could facilitate effective learning (Koehler and Mishra, 2009; Daughtery and Berge, 2017; Rosenberg and Koehler, 2015). In light of this fact, even in the area of science education—where science and technology are supposed to have been acknowledged as advantageous (Waight and Abd-El-Khalick, 2012), technology is mostly serving as a supplement, scaffold, or a secondhand substitute for more traditional modes of education (Zhai et al., 2019b). Science education is still suffering from a lack of robust programs to underpin innovations driving workforce development in the future job market (Lobanova and Glushko, 2016).

To cope with such an educational dilemma, the authors of this paper argue that technological innovation could make sense for learning only if embedded in appropriate pedagogy. A similar argument has been made by Crompton and Burke (2018) after reviewing the use of the most updated mobile technology in higher education. While Crompton and Burke identified such a gap between potential and current reality, they did not specify what they saw as the most critical pedagogical aspects of mobile learning. In this paper, we introduced a pedagogical framework for mobile learning developed in the course of our multiple-year project by considering three critical aspects:

- The degree to which technology is integrated with learning activities
- The roles that students and teachers play
- Learners' perception of the technology

We elaborate this argument drawing on data and evidence from literature that particularly focused on the use of mobile technology in science classrooms, including our publications (e.g., Zhai et al., 2018, 2019a,b; Zhai and Shi, 2020). In the following sections, we first review mobile learning in science education. We then articulate a three-dimensional pedagogical framework including the three critical aspects mentioned above. To support this framework, we synthesize evidence for each of the three

dimensions from literature. We conclude with four implications for science educators seeking to better implement mobile technology to facilitate science learning.

Mobile learning in science education

Mobile learning has been a new paradigm in science education. Grant (2019) examined existing definitions of mobile learning and summarized four major categories: relationship to distance education and e-learning, exploitation of devices and technologies, mediation with technology, and the nomadic nature of the learner and learning. These definition categories reflect significant variability in mobile learning which should be grounded in the characteristics of specific disciplinary and research purposes. In science education, students may utilize mobile technology such as tablets or cellphones to solve problems, design solutions, and demonstrate thinking. Such learning may be remote or in-person and can be in formal or informal learning environments (Delen and Krajcik, 2017). Mobile applications in science education have the potential to advance audiovisual representations, increase location awareness, and make virtual learning possible almost anytime and anywhere (Zydney and Warner, 2016; Zhang et al., 2010). Most of these mobile applications, as reviewed by Crompton et al. (2016), yielded positive learning outcomes, drawing great interest in science education. Mobile applications have demonstrated multiple advantages over traditional educational technology in science education, such as portability, accessibility and affordability, multifunctionality, ease of use, and compatibility.

Portability

A fundamental goal of science educators is to engage students in “answering questions about the world or understanding an observed pattern” (National Research Council, 2012). Achieving such a learning goal largely could depend on how we can guide students directly to observe and investigate science phenomena outside of the classroom. Traditional science learning has been constrained in classrooms and labs because most experimental equipment for data collection and analysis is difficult to move to outside of these locations. Therefore, students must primarily rely on experiences of memorization, imagination, and a limited number of lab demonstrations in the classroom to participate in science learning. This learning structure has changed significantly since mobile technology became more widely accessible and is now being applied to science education (Delen and Krajcik, 2017). Mobile technology such as the recently released iPhone 11 Pro, which only weighs 188 g and can provide up to 20 h of video playback, allows for portable, durable, and high-capacity use in science learning. Mobile technology allows students to experience science learning almost everywhere, including in field settings. In their study, Wallace and Witus (2013) incorporated iPad tablet devices into graduate-level K-12 in-service teacher field-based courses. Students used *AMS Sand Sludge Sediment Probe* installed in iPads to collect field data (e.g., shallow sediment cores in different locations), which was difficult to achieve without mobile technology, and analyzed it later in the lab (see Fig. 1 left). Due to the portability of the iPad, they found that teachers increased their confidence in technology use both as students in their outreach class and in their own teaching.

Accessibility and affordability

Accessibility and affordability have been regarded as two of the fundamental factors in engaging students and teachers in using educational technology (Cuban et al., 2001; Ally and Tsinakos, 2014). Mobile technology has been reported to be the most affordable educational technology ever (Tsinakos, 2013). The Pew Research Center (2019) reported that more than 96% of US adults own a mobile device, such as a cellphone or tablet, that can be used for learning. “Digital natives” at the age of eight or less who are immersed in technology have been reported to spend an average of 2.3 h per day using mobile devices (Bernacki et al., 2020).

Fig. 1 Field learning using iPad (left) and sensors in Phyphox (right).

Even infants and toddlers, as reported by Levine et al. (2019), are frequently using mobile devices for learning. Given such great accessibility and affordability, it is not surprising that mobile devices have been broadly utilized in formal and informal science learning (Lai, 2020).

Multifunctionality

Science investigators need to collect and analyze data to better understand relationships between variables and to construct explanations for phenomena. The data are not always observable to the naked eye and often need technological devices such as sensors to measure relevant variables. Mobile devices can help in this regard as they are usually equipped with multiple sensors that can be used to detect phenomena and convert them to measurable data. For example, Fig. 1 right shows a free mobile phone application, *Phyphox*, that integrates multiple embedded sensors to collect up to 29 types of data in physics. More importantly, the data collected can be represented in various forms. In their study, Becker et al. (2020) engaged students in using mobile applications that could provide multiple representations of measurement data and found this approach reduced students' extraneous cognitive load and increased their conceptual knowledge, compared to traditional physical experiments.

Compatibility

Compatibility denotes the degree to which the technology is consistent with existing uses, need, and values of users. After surveying 200 college students' use of mobile technology for an online course, Chung et al. (2015) found that compatibility is one of the most prominent predictors of students' intention to use mobile technology in college learning. In science education, high compatibility indicates that students would be able to incorporate mobile technology in aspects of scientific inquiry already commonly acknowledged as important. For example, Liu et al. (2017) developed a mobile application, *InduLab*, for scientific modeling. In their study, students used a smartphone to record the changing angles of a pendulum to collect and store data. The data were plotted within *InduLab* for students to model harmonic motion. They found students were positively engaged in the practice of scientific modeling and 90% of them developed a meaningful explanatory model.

Existing technology such as animations and simulations had been broadly adopted in science learning to support students' scientific inquiry, but such applications were constrained to the computer-based learning environment and thus limited to the science classroom environment. Using mobile technology, Al-Balushi et al. (2017) embedded a package with animations and simulations in a mobile app to help students learn chemistry. Students used the mobile delivered simulations and animations to manipulate variable, collect data, and made predictions. After using the mobile application for 9 weeks, researchers found significant differences in spatial ability between students who used the mobile application and those who did not.

Though mobile technology has all of the potential advantages mentioned above, its ultimate effectiveness depends on how students and teachers use the technology. In the following section, we present a three-dimensional pedagogical framework for analyzing such use.

A three-dimensional pedagogical framework

Though mobile learning has been incorporated in science education to a limited degree for decades (Seppälä and Alamäki, 2003; Chen et al., 2003), there has been a lack of a comprehensive pedagogical framework to guide the use of mobile technologies in science classrooms (Li and Wang, 2018; Daughtery and Berge, 2017). In her review study, Bai (2019) categorized mobile learning into nine categories of pedagogical practices, including situated learning, communication and collaborative learning, game-based learning, inquiry-based learning, informal learning, personalized learning, behaviorist learning activities, learning content access and review, student engagement and motivation. However, she did not abstract the major pedagogical theories implicitly underlying the practices. A review study conducted by Zydney and Warner (2016) suggests that much research on the application of mobile learning is grounded in learning theories, most prominently situated learning. Situated learning theorists argue that science learning needs authentic scenarios to allow students to physically experience the phenomena being investigated, and this perspective has assisted many application designers to identify the critical features of mobile technology to better serve science learning. However, this and other learning theories have not yet widely informed teachers and students in regard to how they should apply the technology in learning activities to better facilitate knowledge construction by specifying what kinds of roles students and teachers should play. More importantly, we don't know how students perceive the usefulness of mobile functions and how their perceptions are associated with their achievement (Crompton and Burke, 2018). Therefore, this article aims to develop a three-dimensional framework to articulate how the critical aspects of pedagogy contribute to mobile learning in science education.

The degree to which technology is integrated with learning activities

The first dimension of the framework looks at the level of integration between mobile technology and learning activities. In their seminal research, Koehler and Mishra (2009) suggested that three forms of knowledge (i.e., of content, pedagogy, and technology) which combine to form technological pedagogical content knowledge (TPACK), are essential for teachers to integrate technology in teaching. This model has been broadly acknowledged and cited in educational research partially because it reveals the fundamental

relationships between technology, content, and pedagogy. Effective instruction has to consider how to integrate the technology with the content and learning activities in a form that could engage students in learning (Kopcha et al., 2020). In a recent study, Jeno et al. (2020) specified the nature of the learning goals (i.e., intrinsic and extrinsic) as an anchor to frame their inquiry tasks for biology students. They randomly assigned students into mobile learning (i.e., a mobile app) and traditional learning (i.e., textbook) groups. Their results suggest an important interaction between mobile learning and intrinsic goal-framing for students' intentions and regulation—how teachers frame learning tasks using technology is critical to the students' success in science learning.

Puentedura (2006) employed Koehler and Mishra's (2009) lens and developed a four-level model (i.e., Substitution, Augmentation, Modification, and Redefinition [SAMR]) to describe how technology can be integrated in learning. In a prior study, Zhai et al. (2018) adopted Puentedura's SAMR model (2006) to categorize 20 specific uses of mobile technology into two of the four levels of integration: the Substitution and Augmentation levels (see Fig. 2). They did not find uses in their study at the Modification and Redefinition levels.

Substitution

At the substitution level, mobile technology is used to directly substitute for conventional learning activities without functional improvement. In their study, Zhai et al. (2018) found that functions such as *My Textbook* was typically used at the substitution level. According to their interview with the lead physics teacher and the authors' close examination of its function, *My Textbook* was simply a digital media representation of the hardcopy of the textbook. Students were able to review the textbook, search content, or make notes on the textbook, but the digital textbook did not include new functionalities. Similar substitution functions included Discussion Aid and Picture Uploading: The former was used to provide resources for discussion which were primarily presented in other forms (e.g., teacher-provided slides) in traditional classrooms; the latter was used to upload students' drawings or pictures to share with others, traditionally achieved by asking students to share their work on the blackboard. These uses have not contributed to functional improvement in conventional science learning.

Augmentation

Mobile technology at the Augmentation level is used to substitute for conventional learning activities with significant functional improvement. For example, there was a mobile function described in Zhai et al. (2018) called *Class Note*, a substitute for traditional note taking. Moreover, it provided functional improvement in allowing students to reorganize, tag, and modify notes much more

Fig. 2 Technology integration model. Modified from Zhai et al. (2018), Puentedura (2006).

efficiently. In Zhai et al. (2018) survey, seventeen specific uses of mobile technology in physics classrooms were classified at this level. These functions represent a higher level of integration with student learning activities than simple substitution.

Learning outcomes varied at different levels of mobile integration

A higher level of mobile integration indicates that the learning activities are better accommodated with mobile technology, indicating greater opportunities for learners to achieve learning goals. Empirical research has shown such potential in mobile learning. For example, to examine how the different levels of integration were associated with students' physics learning achievement, Zhai et al. (2019a) collected students' frequency of use for each function, as well as other information (e.g., demographic, learning achievement and interest), from 803 high-school physics students. According to a multi-level covariate analysis, they found that these mobile technology uses (e.g., *substitution* and *augmentation* uses) could explain 5% of the total variance of students' physics learning achievement. This finding is aligned with assumptions in prior research that the integration levels matter to learning efficacy (Puentedura, 2006). Further analysis found that the frequency of *augmentation* uses had a significant positive correlation with student achievement. However, Zhai, Li and Chen did not find a significant correlation of the frequency of *substitution* uses with student achievement. This result suggested that a higher level of mobile technology integration yields greater physics achievement (for details see Zhai et al., 2019b).

Even though mobile integration levels are critical to the efficacy of using mobile technologies, it is unlikely that teachers would be able to develop high-level of mobile integration learning activities without professional learning. This is because a higher level of integration design would require teachers to have TPACK to transform content knowledge to practice knowledge in designing learning activities that utilizes the advantage of mobile technology. Such discipline-dependent practice knowledge is not likely to be inherent in teachers' general professional preparation. For example, after examining college faculty use of one-on-one iPads in their classrooms, Cavanaugh et al. (2013) found no statistical difference in terms of numbers of teachers between those who designed the Substitution-level learning activities and those who designed higher-level learning activities. Teachers at all levels may only use mobile technology as a substitute rather than to transform learning. Therefore, efforts to support teachers to develop TPACK in specific disciplines are needed.

Pedagogical roles that students and teachers play

Much recent research on pedagogy has highly focused on the roles of students and teachers in processes of technology use (Li and Wang, 2018). This is partially because learning is deemed as not only a psychological but also a social process (Richardson, 2003). While the psychological aspect looks at the developmental characteristics of learning and how students' learning progresses with the support of teachers and technology, the latter aspect focuses on the authority and identity of students and teachers and how their identities may interact with knowledge acquisition and construction. We value both aspects but focus on the latter aspect for this mobile learning research because we regard the primary function of technology as assisting in building a social learning environment. Students have to interact with the environment in order to develop their knowledge and achieve learning goals. Teachers, though, can also use technology to shape that environment, playing a role in facilitating students' learning and help students achieve their learning goals. To have a meaningful interaction with the environment, it is critical to examine the roles of students and teachers play in terms of how they use the technology (see Fig. 3).

In a prior study, Zhai et al. (2019a) classified students' technology uses into three types according to "who leads the use." They acknowledge that the uses may also depend on the specific learning content and situation. One given function may be led by students in one activity but by teachers in another one. Therefore, the classification was based on teachers' typical uses in their specific classrooms.

Student-led technology

In this mode, students have authority to determine when and how to use the technology in specific learning activities, self-regulating their own learning pace as needed. Students are active technology users rather than users passively engaged according to teachers'

Fig. 3 The STC model. Adopted from Zhai et al. (2019a).

instruction. Note, however, that active technology use does not equal active learning—it is possible that students actively engage in technology use but not knowledge building, even though this type of uses is a trend in mobile learning.

Wang et al. (2020) developed a context-aware plant ecology learning system (CAPELS) to support students' field learning of plant ecology. CAPELS adapts machine learning algorithms to automatically identify plant leaves. While conducting field learning, students could utilize the CAPELS to identify leaves and collect information whenever they felt confused. This implementation is led by students and teachers had limited input in this process, and the study found CAPELS effectively improved students' motivation and learning performance.

In their study, Zhai et al. (2019a) classified student use of the mobile app *Mindmap* as a student-led function. Their research suggests that students primarily used *Mindmap* to construct concept maps for topics and to establish relationships between topics. When learning new concepts, students would revise their concept maps to connect new concepts with their old knowledge structure. Though students did not use *Mindmap* in every class, they constructed or revised concept maps after completing a unit or revisited the concept maps whenever they felt confused by some concepts. Their physics teacher usually spent time to help students understand what concept maps are and how to use *Mindmap*. Teachers also suggested students develop concept maps for each topic, or graded student concept maps, but they seldom explicitly indicated to students when to do so. It was up to the students to decide when and how to use *Mindmap* in their physics learning.

Learning with *Mindmap* was primarily self-regulated by students. Teachers might have included instruction at the beginning of a learning unit or monitor students' uses of the application at its end, but they would not intervene to influence the frequency or timing of students' use during the course. Students had full authority to determine when, where, and how to use the technology. This type of freedom allows students at different learning levels to personalize their learning. For example, lower-level students may want to spend more time on revisiting *Mindmap* than higher-level students when not constrained by any rules.

Note that "student-led uses" of technologies may also be embedded in structured learning activities, in which students have very limited flexibility in leading mobile learning activities. For example, Ahmed and Parsons (2013) described the mobile app *ThinkLearn* and how they implemented this app in abductive science inquiry. Students used the app during four learning phases: exploration, examination, selection, and explanation. However, all the learning activities were ordered by the teacher, and students were involved in a series of linear activities. In this situation, the effectiveness of mobile learning will largely depend on the design of the learning activities. Therefore, we should consider students' authority in not only the use of mobile devices, but also in the larger context of the learning activities.

Teacher-led technology

In this mode, technology is primarily developed and used to support teachers' instructional activities. Often, teachers initiate and direct use of the technology in the technology-enhanced activities, leaving little or no opportunity for students to direct the use of the technology. In their prior study, Zhai et al. (2019a) described a mobile function named *Doodle* used by students and teachers in physics learning. By using *Doodle*, students could draw models, take screenshots and submit them to teachers. For example, in teaching the concept of acceleration to high school students, the teacher broadcast a video on student tablets showing how a motor and a plane accelerate when they start to move. He then asked students to make screenshots at time 2 s, 4 s, 6 s, 8 s, and 10 s using the *Doodle* tool, and then draw arrows to represent the speed of both the motor and the plane. Students watched video, made screenshots, drew arrows, and submitted their "doodles" to teachers following teachers' instructions. In this example of using *Doodle*, the teacher initiated the use and instructed students to do exactly what he wanted students to do. Students had almost no authority to determine when and how to use the function, even though they used the function to actively add in their own drawing. This use had constrained students' freedom of use and seemed primarily to serve for the teacher to organize the instruction.

Some studies suggest that this teacher-led mode may have less impact on students' learning performance. For example, Lee et al. (2019) investigate the use of an instant response system *Kahoot* in middle school earth science. They found no significant difference in terms of learning motivation, value of earth science, expectation of earth science, and learning outcomes between students who used *Kahoot* in the experimental group and those in the control group. This is not surprise as students were purely passively involved in the mobile learning and there is little functional improvement provided by the mobile function compared to traditional learning.

Collaborative technology

When both students and teachers actively participate in the mobile learning, technology use becomes a medium to connect students and teachers in learning activities. In this mode of technology use, either students or teachers may initiate the use while the other may follow and give active input on their use of the technology. The major characteristic of collaborative technology use, as compared to student- and teacher-led functions, is that both students and teachers play active and significant roles. Note that collaborative technology use is different from collaborative learning, which emphasizes collaboration between students. In their research, Zhai et al. (2019a) found the digital *Learning Guide* was frequently used in a collaborative manner, with teachers and students both actively involved. Sometimes teachers required students to preview *Lesson Guide* before class—teachers played a lead role in initiating the use. However, students also spontaneously referred to *Lesson Guide* because they found it useful in many ways. For example, students might raise questions when reviewing the *Learning Guide*, and they would make notes on it or send a message to their teacher. Teachers could reply responsively to their questions because of the high accessibility of mobile technology. Mobile apps like the *Learning Guide* plays a significant role in connecting teachers and students.

Student-led and collaborative functions outperform teacher-led functions on student achievements

Consistent with constructivist views of teaching and learning, student-led functions and collaborative functions both actively involve students in mobile learning, though to a varying degree. Student-led mobile functions require students to be most actively involved in science learning, compared to collaborative and teacher-led functions. Therefore, students who frequently used this type of functions are expected to outperform other students, and empirical evidence supports this. For example, Zhai et al. (2019a) examines the effectiveness of the three types of mobile technology uses. In their study, Zhai et al. (2019a) classified 15 specific mobile functions into three groups according to “who led the use.” They conducted an analysis of variance on achievement scores using the class as a fixed independent variable and controlling for the pretest score and found that there is a significant main effect of class on student post-test achievement. After controlling for students’ gender and the pre-score, student-led functions and collaborative functions both significantly predicted students’ physics achievement, but teacher-led functions failed to offer that prediction. Their results suggest that for one standard deviation increase of student-led functions of mobile technology use, student achievement increased 0.20 standard deviations, higher than for collaborative function use (0.08 standard deviations). This finding explicitly supported their prediction.

Student perceptions

Student perception of technology has been regarded as one of the most crucial factors that may impact how technology is used in the classroom (Ferguson and Bargh, 2004; Karahanna and Straub, 1999). This insight also applies to mobile technology in science education. According to their review, Crompton and Burke (2018) suggested that 29% of mobile learning studies they reviewed focused on students’ perceptions of mobile learning. This finding is not surprising as student-perceived usefulness has been found to be a factor that may influence student behavior. The question remains how students’ perception is associated with frequency of technology use and student learning outcomes.

The learner’s perception of technology is critical and may be moderated by factors such as the roles that students and teachers play in mobile learning. In their study, Zhai and Shi (2020) developed a path model accounting for this mechanism. In the model, they used student physics learning interest and prior physics learning scores as covariates and examined how the frequency of use of 15 mobile functions directly and indirectly predict physics learning outcomes (see Fig. 4). Given that male and female students may have different perceptions of mobile technology (Wang and Wang, 2008; Wang et al., 2009), they applied a multi-group structural equation model to analyze the data collected with a total of 803 high school students. Their findings suggest that perceived usefulness was a significant predictor for use frequency by pedagogical category for both male and female students. They found that the student-led and collaborative functions had smaller coefficients than that of teacher-led functions for both groups—when teachers, as compared to students, have greater authority in classroom in terms of directing the frequency of technology use, student perception of the technology matters less.

Student gender may moderate their perceptions of the mobile usefulness. Zhai and Shi (2020) suggest a significant total effect on student physics achievement of student perception of collaborative functions for male students, while student perception of student-led functions had a significant total effect for female students. The findings suggest that male and female students’ perception may result in different learning outcomes due to their roles in the uses of mobile technology. For both male and female students, the perception of teacher-led mobile functions had a total negative effect on student physics achievement.

Remarks

While earlier research was concerned with the paradox of “high access and low use” (Cuban et al., 2001), mobile technology is now advancing to the stage of “high use and high effectiveness.” Recent research (Zhai et al., 2018) has indicated that mobile technology, differentiated from other electronic technologies, is now frequently used in science learning. “Low use” has not yet been a concern for mobile technology due to its multi-functionality, portability, and accessibility. The concern became how to make use of mobile technology to facilitate effective science learning. This article provides a comprehensive pedagogical framework for us to better understand the uses of mobile technology in science learning.

Fig. 4 Theoretical path model. *Note.* PH_I = physics interest, PU_S = perceived usefulness_student-led, PU_T = perceived usefulness_teacher-led, PU_C = perceived usefulness_collaborative, UF_S = use frequency_student-led, UF_T = use frequency_teacher-led, UF_C = use frequency_collaborative, Po_PH = post physics achievement, Pr_PH = pre physics achievement. Adapted from Zhai and Shi (2020).

We acknowledge that with the advent of wide availability of mobile technology to nearly all teachers and students, it becomes increasingly realistic for science teachers to broaden their vision of settings appropriate for formal science learning to incorporate field settings, including not only the types of locations where professional scientists might gather research data, but also the homes and local communities of students. However, understanding how to better implement mobile learning in science education is critical (McMahon et al., 2016). Prior research has highlighted the importance of pedagogical context in mobile learning (Dennen and Hao, 2014; Aguayo et al., 2017; Li and Wang, 2018); yet no research has explicitly developed a comprehensive framework to help researchers and educators in science to understand this novel learning opportunity. Such a framework is especially valuable since the COVID-19 pandemic has significantly impacted schooling and many students have had to rely on remote learning (Bond et al., 2020). Without such a framework, mobile technology may not be used appropriately or perceived as useful in science learning, especially when more students are learning remotely than ever before during this critical pandemic time. The framework provides such a vision for understanding mobile learning and has implications for the following aspects of it.

First, mobile technology, with all of its advantages (over full-size computers) in portability, accessibility, affordability, and multifunctionality, is unlikely to improve science learning unless its use substantively and qualitatively enhances the capabilities of students to engage with scientific ideas. Providing a more convenient substitute for functions normally or previously carried out by teachers and/or students (either with full-size computers or in “low-tech” fashion) without its assistance is not sufficient for measurable improvements in achievement. This knowledge should help science educators to *develop learning materials and activities that are deeply integrated with mobile technology*. Such uses should prove especially valuable for engaging students in scientific practices such as modeling, argumentation, and computational thinking using mobile technology, in classroom, field, or remote learning spaces (Liu et al., 2017; Hwang et al., 2013).

Second, student-led functions of mobile technology—that is, those for which students, rather than their teacher, are in control of at least the timing and frequency of their use in science learning (if not, in practice, often the nature or purpose of their use)—are more likely to lead to increased learning, if the mobile devices are used often, than teacher-led functions—those based on prescriptive, inflexible instructions from the teacher—even if the students are operating the devices rather than merely observing them used by their teacher. Collaborative use of mobile technology, in which the devices provide a means for students and teachers to initiate (from either side of the dyad) and maintain interactive communication, were associated with more modest learning gains in these studies, but their relatively infrequent use suggests that examining classrooms in which they are more common would be a promising future direction for research. Findings in this aspect highlight the roles that students and teachers can potentially play in mobile learning. This dimension of the framework provides a lens for educators to *design their learning activities by coordinating students’ and teachers’ roles in a way that is effective for science learning*.

Third, the framework highlights learners’ perceptions about mobile technology. Though perception has been used before to account for why users accept technology (Karahanna and Straub, 1999), there remains a need to understand how this perception impacts the actual frequency of use and student learning outcomes. The mechanism tends to be complex—that is, high perceived usefulness suggests high use frequency but does not necessarily indicate high effectiveness. This is because students’ perception is associated with not only their use frequency but also their roles, gender, etc. The potential for more profound, truly transformative effects on science learning (major modifications of the design of learning tasks or, eventually, the facilitation of entirely new tasks practically impossible without mobile technology) would require careful simultaneous attention to a large number of factors. No instances of such outcomes were observed in these studies, despite quantitatively demonstrable incremental gains in learning associated with the several promising theoretical frames we employed. Simply assuming a relationship between perceived usefulness and learning outcomes may not work in authentic and complicated science learning environments. This suggests that *multivariate quantitative research studies of affective factors contributing to student achievement* in such exemplary classrooms would probably be premature, and exploratory, descriptive, largely or wholly qualitative studies may be needed to generate new theoretical constructs and/or hypotheses about quantitative effects in such learning environments.

Last but not least, gender differences in science learning have long been of great interest to science educators and have often been posited (and sometimes empirically identified) to be most prominent in physics in particular (Brewer and Sawtelle, 2016). The studies summarized here suggest that further research on the effects of student perceptions of the use of mobile technologies may be a particularly fruitful new angle from which to view the role of gender in the physics classroom, and that emphasizing student-led functions of these technologies may improve the achievement of female students in particular. Specifically, male students’ perceptions of technologies with which students play a leading role in the uses may positively affect their learning outcomes, while female students’ perceptions of collaborative use of technology is a positive predictor of theirs. Thus, educators are strongly encouraged to *implement mobile learning in science in light of the effect of student gender differences in their perceptions, frequency of use, as well as the nature of their roles in technology use*.

Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. This article does not contain any studies with animals performed by any of the authors.

Informed Consent: Not applicable.

Conflict of Interest: The authors declare that they have no conflict of interest.

Introduction

In recent years, there has been widening interest in and opportunities for public engagement with science through citizen science initiatives, worldwide (Bonney et al., 2014). As a collaborative effort in nature, citizen science promotes public participation in scientific endeavors and can bring communities and scientists together around scientific projects that are local to global in scope. Through this collaboration, great potential exists for the advancement of science alongside transformative effects, such as development of individual skills, learning processes and creating a dialog between researchers and participants (see Fig. 1) (Shirk et al., 2012; Turrini et al., 2018).

Citizen science has many origins, from 19th century weather observations to 20th century environmental monitoring, to 21st century big data opportunities. Today citizen science is used to advance research in biology, astronomy, environmental sciences, physics, and other fields. Each project represents a different vision of what non-experts contribute to the production of reliable knowledge about the natural, social, and cultural worlds as well as a vision for building students' capacity for engaging with real life socio-scientific dilemmas.

Organizations that support citizen science initiatives are mushrooming in many places around the world. Here we note for example the USA based Citizen Science Association (CSA), the European Citizen Science Association (ECSA), the Australia Citizen

Fig. 1 The threefold potential of citizen science for generating new knowledge, learning outcomes and civic participation. Source: Turrini, T., Dörler, D., Richter, A., Heigl, F., Bonn, A., 2018. The threefold potential of environmental citizen science—generating knowledge, creating learning opportunities and enabling civic participation. *Biol. Conserv.* 225, 176–186. <https://doi.org/10.1016/j.biocon.2018.03.024>, p. 177.

Science Association (ACSA), the CitizenScience.Asia association and others (websites of all of these organization appear at the relevant websites section at the end of this article). The overarching goal of these organizations is to support the theory and practice of citizen science, as they play a critical role in facilitating and establishing citizen science as a field of practice and area of scholarship, and cultivate a new citizen science culture (Storksdiack et al., 2016). The institutionalization of citizen science is also broadening with recognition by policymakers and funding agencies, the launch of a specified citizen science journal and several professional and practitioner conferences.

The book *"The Science of Citizen Science"* (Vohland et al., 2021) published by the citizen science COST action, outlines the various aspects of citizen science and reflects on the contribution of citizen science to societal development, education, and innovation. Using a holistic approach and viewing citizen science as a social and civic enterprise, multiple stakeholders of citizen science are outlined, from scientists to citizens and from policy makers to environmental organizations. In addition to the contribution of citizen science, the book deals with ways to improve citizen science practice and discusses its scientific quality, data standardization, use of technologies, participant motivations and developing synergies with education systems.

To this end, Kloetzer et al. (2021) discuss the diverse ways in which participants of citizen science learn and the many settings in which such learning can take place. These include online settings, museums, community engagement, families and formal and out-of-school education settings. Because citizen science opens new opportunities for science learning, especially when conducting scientific inquiry with students (Bonney et al., 2014), these projects are becoming more and more popular in the field of science education. Schools, students, and teachers are increasingly seen as important stakeholders of citizen science and dedicated programs are created for incorporating citizen science in schools (Shah and Martinez, 2016; Harlin et al., 2018).

The goal for this article is to discuss the potential for incorporating citizen science in schools for promoting science education, active citizenship, and a vision of science as relevant and important to students' daily lives. As we sketch out the web of potential educational benefits citizen science has to offer, we illustrate a lively science education arena, in which students and schools actively engage with science through citizen science, leading to diverse learning outcomes.

Our article is designed to elicit a discussion about the different ways citizen science in schools can promote meaningful and broad learning outcomes, and provide students the opportunities to develop knowledge and skills they need to live in today's scientifically and technologically enhanced society (Ryder, 2001; National Academies of Sciences Engineering and Medicine, 2016).

Through presenting three case studies, representing the varied landscape of citizen science projects in schools, we will expand upon the many different ways learning can take place and discuss ways in which citizen science can sustain active citizenship and increase student awareness and relatedness to science.

Learning through citizen science

Research into learning opportunities through citizen science reveal diverse learning outcomes from student participation. These may include cognitive dimensions (what people know), affective dimensions (what people feel) and behavioral dimensions (what people do) (Phillips et al., 2014). Citizen science enables students to engage in hands-on, authentic research and learn about science from broad perspectives. A variety of individual learning outcomes from citizen-science have been documented. These include interest in science and the environment; self-efficacy for science and the environment; motivation for science and the environment; increased scientific knowledge; skills of science inquiry; and environmental stewardship (Phillips et al., 2018). At the same time, how this learning takes place and what factors are involved in these processes are not well understood. Furthermore, while some participants in citizen science projects have demonstrated increased content knowledge and scientific skills, higher level learning and increased understanding of the Nature of Science (NOS), its relevance to day-to-day life has not been documented in school context.

In 2018 the National Academies of Sciences, Mathematics and Engineering published a consensus report: *Learning Through Citizen Science: Enhancing Opportunities by Design*, that set out to examine the complex relationship between the potential of citizen science for science education and the way this potential is fulfilled as well as to set out the evidence supporting this claim. The report highlights a list of conclusions and recommendations, three of which are relevant to our discussion of learning outcomes. First, the writers conclude that "Citizen science supports learning outcomes related to scientific practices, content, identity, agency, data, and reasoning" (p. 147), however they emphasize that to realize these outcomes the design of the projects needs to be focused on them and some type of support for learning needs to be provided. They stress: "Without intentional design, it can be hard to anticipate what learning outcomes will be achieved" (p. 150). Moreover, the report ends with a recommendation that citizen science projects who wish to enhance learning opportunities need to work toward designing the project in a premeditated way, working with stakeholders and especially those with expertise in education to design the project. Similar findings have been discussed by Roche et al. (2020), who highlight the competing goals of science, learning and social advocacy and call for the alignment of goals through deliberation and co-creation.

In an attempt to support and direct learning outcomes from citizen science, multiple initiatives for incorporating citizen science in schools have been established. Through engaging students in real-world authentic investigations, these initiatives aim to increase student's interest and eventually, learning. Some examples include:

- Taking Citizen Science to Schools (TCSS) center in Israel. A collaboration between two academic institutions linking education researchers, scientists and schools, in an effort to facilitate implementation of a variety of citizen science projects in schools and increase student learning outcomes. TCSS focuses on both the practice of implementing citizen science in schools and the practical knowledge needed for sustaining and enhancing such endeavors. They emphasize on developing research-practice partnerships for ongoing evaluation making projects relevant and beneficial for multiple stakeholders, especially schools.

- The citizen science platform in the New Zealand science learning hub. This is a digital platform designed for teachers who are interested in incorporating citizen science in their classroom, offering teachers relevant projects, proposed classroom activities and dedicated lesson plans. The platform also offers webinars on citizen science and allows teachers to tailor the educational work to specific scientific skills they are interested in.
- Cornell Lab of Ornithology- K-12 Education Team. The Cornell lab is one of the pioneers of citizen science in North America. Their education team is devoted to creating resources for both formal and informal education teams, using an inquiry-based approach to connect students to their local habitats and build their science skills. The Cornell Lab K-12 Education team offers teachers professional development opportunities and educator's guides as well as curriculum-based activities for students and activities for children out of school.

These initiatives, among others, are focused around learning outcomes and developing scientific skills. They demonstrate the growing interest in incorporating citizen science into formal education systems as mentioned in the report above, and the vast potential for increasing long term learning outcomes. But can citizen science go beyond conventional learning outcomes, promoting critical thinking and urging students to realize the complexity of science as a real-world endeavor? This will be the focus in the next section of this article where we further explore the potential of citizen science for promoting a holistic view of science, civic action and democratic participation.

Citizen science in schools—exploring a broad potential

In a paper published a few years ago in *Science Magazine*, citizen science was suggested as a form of collaborative research among scientists, educators, and the public (Wals et al., 2014). Wals et al. (2014) argue that citizen science might lead to more effective processes of public engagement and learning that could stimulate meaningful socio-ecological outcomes. In the “post-truth” era where trust in science seems to be diminishing, formal education can benefit from becoming part of new hybrid forms of knowledge co-creation, that seek to contribute to a more sustainable world. Furthermore, with such ill-defined, highly contextual and ambiguous key issues of our time (also described as wicked problems that are difficult to solve because of incomplete, contradictory, and often changing and undefined requirements), alternative forms of research and inquiry are required. Citizens, including younger generations, need to have agency; access to multiple knowledges—including scientific knowledge, indigenous knowledge and local knowledge—and the opportunity to reflexively act to improve a situation jointly with the multiple stakeholders affected by an issue (Wals and Peters, 2017).

However, to realize this vision, a more holistic approach is needed for ways to engage learners for optimal individual and community outcomes. Learning which goes beyond scientific knowledge and incorporates social dimensions, cultural awareness and individual responsibility. In this section we will focus on three important aspects that contribute to meaningful impact of citizen science projects in schools and to broadening the learning outcomes. These include (a) learning about Societal Aspects of science, (b) raising Awareness to science and the environment and (c) engaging in Action on the local and global level (SAAA). We will then introduce three case studies that demonstrate how these aspects play out in three citizen science projects of distinct nature.

Societal aspects of science

Science, or rather the scientific method, is comprised of diverse practices and concepts that collectively aim to minimize error and provide reliability and reportability to a study (Bauer, 1994). The value of this practice is in developing a culture or mindset of thinking both analytically and critically about complex situations. It provides the ability to make logically deductive arguments from simple premises, and identify salient variables, patterns in data and numerical fluency (Claussen and Osborne, 2013). These scientific practices take into consideration a number of core ideas and concepts, which are fundamental for scientific inquiry and research, as well as application of science in everyday life.

However, formal science education has a tradition of disengaging science from the real life of students (Feinstein, 2011) and not proving as useful for decision making in later life (Crowell and Schunn, 2016). Many science education researchers offer ways in which teachers can make science more relevant, often by using what has been termed Socio-Scientific Issues (SSI) (Tal and Dierking, 2014; Kinslow and Sadler, 2018). SSI are science-related topics which have a strong social dimension and are often controversial, such as environmental and health related issues. Introducing such issues in a classroom environment is suggested as an effective way to engage students with science while considering its social, cultural and personal relevance.

This is of great importance, since both adults and children encounter “science” in many daily situations and are often expected to make related decisions. Since “[s]cience is never separate from the values of those who have a stake in it” (Mueller et al., 2012, p. 7), it is essential to discuss and teach science from the preceptive public encounters with science and consider their context and culture. Moreover, studies have consistently found that science knowledge is best acquired when it is personally or socially relevant (Shauli and Baram-Tsabari, 2019).

In this context, citizen science offers a platform where science is not disengaged from society and non-experts can be meaningfully engaged in a real scientific endeavor (Mueller et al., 2012). Through such hands-on experiences, participants can make connections between science and daily lives, providing an authentic scientific experience in a day-to-day context and contributing to life-long

learning processes. For example, [Koomen et al. \(2018\)](#) studied middle school students' engagement with a science fair project. One of their key findings was that participating in an authentic context provided at a summer citizen science program, served as a crucial starting point for their future participation in school science programs. Similar findings have been reported following student participation in a local air quality monitoring project with increased contextualized understanding of local air quality hazards and their relevance to students' personal exposure and health ([Golumbic et al., 2016](#)).

Awareness to science and the environment

Research over the past few decades has demonstrated that "raising levels of knowledge does not directly lead to a more positive attitude toward science" ([Edwards, 2004](#), p. 261). Thus, educational programs wishing to truly engage and impact student attitudes, need to adopt an approach that takes this into consideration and develop engagement and skills that go beyond knowledge. One of the processes that enable this is raising awareness of students to the interconnectedness of science to their lives, an important outcome, even if students do not foresee a science related career. Citizen science projects in schools are often designed to elicit exactly that—in depth engagement of students with science relevant to student's lives. Raising awareness and stewardship as learning outcomes of citizen science projects have been suggested widely in the literature ([Jordan et al., 2012](#)).

Public awareness of science and technology is a term coined by [Gilbert et al. \(1999\)](#) to be used in the context of science centers and museums. It is defined as "a set of attitudes, a predisposition toward science and technology, which are based on beliefs and feelings and which are manifest in a series of skills and behavioral intentions" (as cited in [Stockmayer and Gilbert \(2002\)](#), p. 836).

Raising awareness of student to one kind of relevant scientific issues: environment issues, is a long tradition within Environmental Education programs, although it has been acknowledged that this awareness is also dependent upon cultural and social characteristics and context ([Tal and Alkahr, 2010](#)). Two examples below demonstrate how contextualizing science contributes to raising awareness—both as a learning goal and as a platform for further action. First, in a study about community based climate change awareness in the Pacific, [McNamara \(2013\)](#) emphasizes that in a reality where knowledge is changing and expanding constantly, raising awareness needs to consider both who the participants of the project are, as well as their cultural and social background. In a different context, [Braschler et al. \(2010\)](#) who studied an ant monitoring biodiversity project in South Africa, found that students were empowered by realizing the local manifestation of larger global issues, as powerfully described:

Perhaps one of the most significant forms of awareness generated is the realization that many areas close to schools are in a poor condition. Scholars see for the first time the refuse and disturbance in their local environments and how this has an effect on biodiversity. In this way they rapidly come to understand that the global problems they read and hear about more generally, and in environmental lessons, are problems that have their basis at a local level and can, at least to some extent, be resolved at a local level. (p. 25)

In a US based study, [Ballard et al. \(2017\)](#) use the concept of environmental science agency (ESA) to identify ways youth develop and identify their own expertise in environmental science as well as a sense of agency with respect to environmental and community actions. They identified several structures and strategies that supported the development of agency and are unique to community and citizen science contexts, for example: using environmental science as a foundation for change.

Indeed, participation in citizen science projects can and has contributed to heightened awareness of science both on the individual and community levels ([Mueller et al., 2012](#)). By developing students awareness to the relevance of science we empower them to "engage in ongoing debates about local and global environmental and sustainability issues" ([Dillon et al., 2016](#), p. 450). This engagement, or rather call for action, will be discussed in the next section.

Civic action

Citizen science has been discussed in the literature as a gateway to civic action. For example, [Ottinger \(2016\)](#) describes a citizen science project monitoring air-toxics to demonstrate the potential of citizen science for social movements. However, within educational systems it is still not widely acceptable that there is a close link between science and citizenship ([Cooper, 2012](#); [Mueller et al., 2012](#)). Although citizen science projects in schools enable students to take an active role in the learning process, and science is often authentic and contextualized ([Koomen et al., 2018](#)), still promoting action that is beyond the learning process is often limited. [Phillips et al. \(2018\)](#) define an important outcome of citizen science in this sense—one that looks at "behavior and stewardship as measurable actions resulting from engagement in citizen science, but external to the protocol activities and the specific project-based skills of the citizen science project". (p. 10)

Stewardship, as suggested by them refers to action taken by citizen science participants, at both local and global scale, as they become more civically engaged. [Turrini et al. \(2018\)](#) reiterate that "citizen science can empower members of the public to get involved in policy-relevant citizen processes and to gain the knowledge that is needed to do so, thereby fostering deliberative decision-making in societally relevant processes" (p. 177).

Some examples of citizen science projects with a more civic participatory approach can be found in the field of crowdsourcing mapping projects, or volunteered geographic information (VGI) ([Haklay, 2013](#)). In these projects the common protocol is of "a collection of people working independently while responding to the needs of the local communities ..." ([Dalyot and Dalyot, 2018](#)).

In these types of projects participants tend to contribute data that is personally relevant, to solve (mapping and access) problems that are appropriate for them, and often the line between them and the scientist is left blurred (Haklay, 2013).

Despite the fact that more and more researchers see this great potential for citizen science projects to encourage and even facilitate social or civic action, research on the pathways to better civic engagement is quite mixed and often limited (Phillips et al., 2018).

Case studies

As demonstrated above, incorporating citizen science into education systems has the potential to lead to effective processes of student learning as well as promoting active citizenship and increasing student relatedness to science as a day-to-day encounter. Such outcomes have been successfully demonstrated in several citizen science projects and are further articulated in the next section, using examples from three distinct citizen science projects.

Enhancing learning and environmental stewardship through citizen science: the case of the radon home survey

Student's learning trajectories and development of social and environmental stewardship has been documented in the environmental citizen science project the Radon home survey. Initiated jointly by environmental and educational researchers, the project based in Israel engages students and communities in measuring and mapping Radon concentrations in buildings, and aims to raise awareness and create mitigation opportunities for lowering indoor Radon concentrations (Tsapalov et al., 2020).

Radon is a dangerous radioactive gas that, in high concentrations, can cause lung cancer. While early detection enables mitigation, many citizens are not aware of its presence, since Radon is both colorless and odorless. Using a simple and cheap technology for passive air absorption, the Radon home survey involved school students in measuring Radon in their homes. Following a series curriculum-based lessons, students learned about Radon gas and its dangers, engaged in class discussions, and analyzed the data received from their measurements.

Research examining the learning processes of students involved in the project and their contributing factors, revealed six common themes which were expressed at different stages of student participation (Columbic et al., 2022) (see Fig. 2). Together, the six themes illustrate a process students experienced throughout their participation: While initially unaware of Radon and its dangers, the students have recognized its relevance to their life, become curious of the topic, motivated to learn about it, and expressed interest in promoting awareness of Radon in their local environment.

The first two themes identified—relevance and identifying unawareness—demonstrate students initial exposure to the project topic and their recognition of its importance and lack of awareness in their close environment. This new understanding inspires the next two themes—interests and experience—as students spark new interest in learning about the subject, and do so in a nontraditional way by engaging in citizen science. This unique experience of learning through hands-on involvement, increases again the desire for learning and stimulates the ongoing interest. Collectively these processes lead to the fifth theme—learning—which is achieved by studying the subject in the classroom, performing Radon measurement and data analysis, and engaging in class

Fig. 2 Six themes which emerged from the data analysis, illustrating the typical learning process in the radon survey. Modified from Columbic et al. (2022).

discussions. Students build their knowledge base about Radon gas, develop an understanding of the importance of its measurement and learn to think critically about socio-scientific issues.

Lastly, after developing an understanding and awareness to Radon, students developed an organic interest in promoting awareness to Radon in their local communities and in becoming agents of change in their close environment. For example, students from one school initiated a community event in order to present the results of their research and raise awareness to Radon in the broader community. Some students suggested that they have a personal responsibility toward their family and community in addressing this matter. Finally, many of the students raised questions about social norms and democratic processes, investigating the role of governments and decision makers in maintaining public health and well-being.

The findings of this study emphasize the potential of citizen science in raising awareness to environmental hazards, empowering students and publics, and promoting their environmental stewardship and responsibility. It eludes to the potential of citizen science in supporting learning outcomes that are beyond formal curriculum requirements and develop student's accountability, forming the next generation of responsible, caring citizens.

Learning about the complexity of science through citizen science: the case of breaking good

Student's learning about the complexity of science and its multifaceted nature, is a key goal of the open source drug discovery project Breaking Good. The project, operating in Australia, the UK and the US, engages students and citizens in synthesis processes of new and existing molecules for human health, and in the investigation of access to important medicines for people around the world (Motion (nee Williamson), 2017).

Such essential medicines have been defined by the World Health Organization as medicines that satisfy the priority health care needs of the population, and should be available at all times, in adequate amounts and at affordable prices. However, there are several barriers which prevent the accessibility of such medicines to people around the world. These include low market incentive, competition and profit considerations, supply shortages, in addition to a range of societal and political challenges.

This complex system provides the Breaking Good project, good grounds for student learning about science and its broader societal context. It inspires a deep conversation about science and society, challenging students to think about essential medicines in broad public health context and consider its relevance to their own lives and communities. Building on this understanding, students engage in drug discovery by learning organic chemistry and following pharmaceutical procedures for molecules synthesis.

Over the past years, high school and undergraduate university students have engaged in Breaking Good, through hands on synthesis of molecules, as part of their teaching laboratories. Rather than throwing away their samples at the end of class, students worked on the synthesis of novel antimalarials drugs, sending their samples for activity screening against malaria. This process resulted in a number of novel molecules which showed promising activity at killing the malaria parasite, contributing to the Open Source Malaria (OSM) consortium which works to speed up and reduce costs of malaria drug identification (Motion (nee Williamson) et al., 2016).

In another case, high school students from Australia reproduced an existing medicine for treating toxoplasmosis (a parasitic infection), that has been price-hiked earlier that year, making it unaffordable for many people around the world. This project is a proof of concept and exemplifies how much can be done to promote science and public health by young and inexperienced scientists, given the right facilities, instruction and personal incentive.

Students have also discussed global production of medicines, equity and resource distribution in medicine and health care and learned about the social, political and financial variables which affect access to some medicine. Such learning opportunities provide a holistic understanding of the complexity of science and the many factor which may influence its development and acceptance.

The classroom as a platform for community engagement: the case of Food Science Class

Citizen science, as a collaborative social and scientific effort, has the power to bring together scientists and communities to work together on relevant issues. This is an especially crucial point when it comes to food science and food literacy, however "citizen science" is rarely discussed in this context (Ryan et al., 2018). The FoodScienceClass project brings together citizen science principles to demonstrate the multidisciplinary nature of [food] science.

This is a collaborative multi-disciplinary project-based learning program that is centered around student led research into the origins of their commonly consumed industrialized food items (e.g., breakfast cereals, yogurts, ketchup, etc.). The project targets young teenagers (ages 13–16 in middle school) at a stage when they start making independent food choices. This is also an age where interest in science is slowly decreasing (King and Henderson, 2018), hence one of the goals of this project is to demonstrate the relevance of science to every day decision and issues—especially on a societal level.

In more detail—the project seeks to engage teenagers with food science processes, social dilemmas, and policy aspects, but at the same time teach them science communication skills. In the context of civic engagement, the component of science communication skills is extremely important as they enable teenagers (now and later in life) to engage with their communities on relevant scientific issues. Thus, students are perceived and addressed as empowered citizens, capable of communicating societally significant scientific issues. Since the programs runs in parallel both in Israel and in Poland, it presents additional opportunities to discuss global vs. local issues within a formal class setting. This poses a rare opportunity in education systems everywhere.

FoodScienceClass project introduces to students the inter and multidisciplinary aspects of food science (and science in general) and strives to make both the subject matter and skills gained relevant to their lives. Throughout the project a strong emphasis was put on the question: “how is this relevant to my daily life?” and students were encouraged to critically consider and discuss this question. For example, when conducting a lab on yeast fermentation (See [Box 1](#))—a chemistry related activity—students discussed industrial uses of yeast and how their conclusions from the experiment are related to cooking at home.

Box 1 Excerpt from info-sheet students receive as part of their yeast experiments

The importance of yeasts in the food industry

Yeasts are vital microorganisms in the food industry. The Bakery yeast (which is also known as the Brewers' Yeast), *Saccharomyces cerevisiae*, and its different species is the most common in the making of food products. Without yeasts, the dough will not rise (sour) and baking goods that we all know and love, like bread, cakes etc. will not exist. When the dough is in its rising stage, which is mostly an anerobic stage, the yeasts ferment the sugar in the dough (which is the flour itself, when no sugar is added) and emit ethanol and CO₂, which is carbon dioxide. The gas emitted fills the dough with air and makes it rise, and the ethanol, which evaporates in high temperatures, gives the dough its special flavor of baking goods.

The use of yeast in baking and the making of alcoholic beverages is believed to be earlier than the invention of script. An ancient clay tablet from Babylon dated 8000 years ago and Egyptian hieroglyphs from ancient Egypt dated 5000 years ago, indicate the existence of these processes, but without the understanding of how they occur. It is believed that dough fermentation began with a coincidence contamination of flour by the bakery yeast which fermented it, giving it its unique qualities.

Although not a traditional and scientist led citizen science project, this project is conceptualized around “problem-based learning” experiences that are known as a useful and important tool in supporting students in gaining knowledge and skills, especially in the sciences ([Willard and Duffrin, 2003](#)). The problem being industrial food consumption in their communities and its effects. They start by understanding what industrial and processed food is, continue with developing a survey to assess the consumption and habits in their families and community at large, and then distribute and analyze the survey. While discussing the survey findings they come up with ideas for further activities and questions, compare results with classes in another country and learn more about the most popular items in their community. Finally, they receive expert science communication training and are then asked to prepare their own communication or outreach activity to disseminate what they have learned in the project.

Since this project is not based on lectures but rather on self-learning and group work, the transition of education systems to remote online learning during the COVID-19 pandemic has not halted the implementation of the project. The fact that project staff were flexible and worked with schools to accommodate needs and logistics demonstrates an important design principle that contributes to success of such projects—working with stakeholder to adjust and fit the program to their need is instrumental.

Integration

The three case-studies presented above, represent a range of citizen science-based projects in various scientific fields, implemented within school environments. While each aims to enhance student knowledge in its respected field, they all have additional learning outcomes they plan and strive for, which include improving student skills, critical thinking and stewardship. Together, these case-studies exemplify how student participation in citizen science can go beyond content knowledge generation to include learning about Societal Aspects of science, raise Awareness to science and the environment and engage in Action on the local and global level (SAAA) (See [Fig. 3](#)).

The Radon Home survey discusses science in the context of daily life, encouraging students to recognize the relevance of the topic studied to their own environments (Societal Aspects). By doing so, it raises students' awareness and inspires their continued interest in learning about the topic and conducting relevant measurements (Awareness). Lastly, and interrelated to the two processes above, students are inspired to take action and positively impact their communities and families (Action).

Breaking Good has a strong emphasis on public health and the social, financial and cultural influences on health care, revealing science research and practice are very much embedded in society (Societal Aspects). It confronts students with the complexity of health systems and science more generally, broadening their perceptions and perspective of “how science works” (Awareness). Finally, it calls for students to assist in the creation of new, open sourced medications and become advocates of such collaborative science (Action).

FoodScienceClass connects students to science through one of the most common activities we all do—eat. It exemplified how interconnected this experience is with food science processes, social dilemmas, and policy aspects (Societal Aspects). By raising students' attention to different ways of food production, marketing and advertising, the project helps student make informed

Fig. 3 Framework for potential of citizen science for engaging students.

decisions and think critically (Awareness). The project also teaches important science communication skills, encouraging students to share this understanding within the community to create change (Action).

Summary

This article discussed incorporating citizen science into education systems for encouraging more effective processes of learning science in the context of real life experiences and broadening students learning outcomes. Using three case studies of distinct nature, we demonstrate the potential for learning outcome in three important aspects of science education; Societal Aspects, Awareness, and Action (SAAA), which go beyond content knowledge generation. We further describe the pathways for such learning to occur, rooted in the continued effort of educators and project facilitators to design for these causes.

While broad in scope and expressed in a variety of contexts, SAAA demonstrates that “by providing both detail of specific science knowledge and also examples of contexts in which such knowledge is important” (Ryder, 2001, p. 2) comprehensive and broad learning can occur. Eluding to the vast potential of citizen science for effective and meaningful learning processes.

However, to fulfill this potential of citizen science several prerequisites must occur. First and foremost, projects need to plan for the educational goals of SAAA. Without such intentional design and consideration of learning goals and processes, it is unlikely to achieve many of these goals (National Academies of Sciences, Engineering and Medicine, 2018). Second, projects must make explicit to participants the scientific, social and cultural issues that they are encountering. This goes beyond explaining scientific processes of data collection to an in-depth justification of the project rationale, values and end goals (Brossard et al., 2005). Lastly, students’ interaction with scientists as well as with the entire scientific protocol needs to be considered in order to allow students to fully benefit from their participation and connect on a personal level. This is increasingly important as many citizen science projects are used as a pathway for data collection with little or no direct interaction with the researcher behind the project or with the complete scientific process (Mueller et al., 2012). Ultimately, in order for citizen science to become meaningful in science education, it has to offer a variety of avenues in which open, collaborative and complex initiatives can emerge. We call for further advancement of citizen science practices, which design for, with and toward the progression of learning on all its complexities.

Acknowledgment

The ideas for this article came from part of our work on a symposium for NARST annual conference 2019. We are thus grateful for the contributions of—Ayelet Baram-Tsabari, Tali Tal, Bruce Lewenstein, Heidi Ballard, Caren Cooper, Arjen Wals and Anne Bowser. We would also like to thank Yael Barel Ben-David for providing useful comments on this article. KD would like to acknowledge the generous support of EIT FOOD in the development and implementation of the *The classroom as a platform for community engagement with food production and science* project.

Introduction

The advancing of STEM education goes beyond reform of the curriculum, teaching and learning in the school setting. There have been calls for more community engagement in STEM education with contributions from families and society. This article discusses the various conceptions and practices related to community engagement in STEM education, supported with research evidence from the literature. This is to engage the community through more public awareness, and to involve the STEM industries/professionals in achieving corporate social responsibilities, to bring real world STEM to STEM education, and to empower teacher professional development to provide quality STEM learning, so as to inspire the next generation with STEM aspirations in their study and career choice.

This article will provide some background information of the STEM education initiatives in the school curriculum and the STEM learning opportunities outside school. It is followed by a discussion of the STEM learning ecosystem with the different individual, family, school and society factors influencing students' STEM learning and STEM aspirations. The various studies on STEM aspirations provide insights into the importance of learning from the community. Some successful cases of community engagement in STEM education will be outlined. The conceptual frameworks of "Establishing STEM Professional-School Collaboration", "Developing STEM Communities of Practice" and "Highlighting STEM professional contribution to the society" are suggested to engage the community more effectively in STEM education.

It is hoped that the suggested frameworks can provide some guidelines for educators and community stakeholders in designing and implementing STEM education. Likewise, it is also timely to have more evidence from researchers with studies on student learning outcomes during the various community engagement opportunities. The evidence will be insightful for educators and community stakeholders and will add knowledge to the related field of study.

Background

In order to prepare our students to engage in innovation and technology, which is one of the main driving forces for the nation's economic growth and productivity, the call for STEM education has become one of the global key educational initiatives. This

development has given rise to active discussions on the forms, strategies and effectiveness of STEM education, not only in the education field, but also among the various stakeholders in the community involved in STEM education.

The substantial energy to improve STEM education is mainly focused on the reform of the existing disciplinary curriculum, teaching and learning, and assessment. The focus on teacher professional development is becoming more intense in its call for a more competent teaching force with relevant knowledge and skills for providing STEM education to students. However, school curricula usually reveal what teachers consider as essential rather than the knowledge and skills that are actually required in the community. Moreover, what should be included in school STEM education also relies on teachers' understanding of what STEM and STEM education are. Unfortunately, STEM is also new to most teachers as they were mostly educated and trained under the disciplinary learning approach.

It is also believed that students do not acquire STEM knowledge or develop STEM skills in schools only, but on many occasions and in different ways after school. For instance, there are STEM learning opportunities during afterschool programs/workshops; when visiting museums and exhibitions; reading (online information or books); watching TV or educational programs; during field trips and outings, or even at home while interacting with peers and family members. These various STEM learning opportunities may interact with and reinforce students' STEM learning in school. Hence, linking education and community is necessary for community economic growth, the advancing quality of life, and promoting citizen's wellbeing.

Gaps between STEM education and required workplace skills have been identified in industry, academia and the government (Jang, 2016). There is research evidence that, although STEM professionals are not educators, their roles in STEM education are indispensable as they have first-hand experience of what knowledge, skills, attitudes and work activities, which can be understood as STEM competence, are performed in their daily tasks. Individual learning is surrounded by layers of influences that have an effect on learning (Olson and Labov, 2014). All of the above diverse influences within and beyond the school setting where STEM learning takes place is conceptualized as the STEM Learning Ecosystem.

STEM learning ecosystem

As STEM learning ecosystems are emerging (Olson and Labov, 2014), there have been discussions of such ecosystems (Traphagen and Traill, 2014), and the ecological framework of factors are influencing students' participation, achievement and progression in STEM studies (Chavatzia, 2017, p. 40).

As suggested in Chavatzia's report for UNESCO (2017), there are multiple and overlapping factors which influence the participation, achievement and progression in STEM studies and careers, all of which interact in complex ways. An ecological framework which encompasses factors at the individual, family and peer, school and societal levels is suggested to explain these factors and understand the interrelations among them.

Olson and Labov (2014) described the concentric circles of influences surrounding the individual learner. Closest to the learner are family, friends, role models, caregivers, mentors, and peers. Beyond these influences, a set of sectors seeks to teach or otherwise provide experiences to learners, including schools, museums, media, libraries, and afterschool clubs. Finally, infrastructural elements such as policies, culture, communities, and values create the rules of the game for sectors as well as individuals.

Similarly, the STEM learning ecosystem suggested by Traphagen and Traill (2014) comprises schools, community settings such as after-school and summer programs, science centers and museums, and informal experiences at home and in a variety of environments that together constitute a rich collection of learning opportunities for students.

The reasons to pursue STEM study and careers may vary among students, ranging from individual reasons such as achieving personal goals, to a greater societal vision such as contributing to the world's advancement (So and Chiu, 2020). Following are discussions of the roles of individuals, family and peers, schools and society in students' STEM learning.

The role of individuals in STEM learning

The role of individuals consists of biological factors that may influence individuals' abilities, skills, and behavior such as brain structure and function, hormones, genetics, and cognitive traits including spatial and linguistic skills. It also considers psychological factors, including self-efficacy, interest and motivation (Chavatzia, 2017). Yet, individual STEM identities have been found to be impacted by both internal and external factors (Hansen, 2018).

Research results have shown that educators, peers, and family influenced youth STEM interest, which in turn predict their STEM self-efficacy and career outcome expectancy. STEM career orientation is fostered by youth-expected outcomes for such careers (Nugent et al., 2015). It was also found in Han et al., (2015) study of 3 years of STEM PBL instruction that low performing students showed statistically significantly higher growth rates on mathematics scores than high and middle performing students. Moreover, high levels of self-efficacy in secondary students have been positively correlated to students' pursuit of post-secondary education (Chachashvili-Bolotin et al., 2016).

The role of family and peers in STEM learning

Family and peer factors comprise parental beliefs and expectations, parental education and socioeconomic status, and other household factors, as well as peer influences (Chavatzia, 2017). Han et al., (2015) noticed that students' ethnicity and economic status

were good predictors of academic achievement. Archer et al. (2013) also found that family exert a considerable influence on students' aspiration.

In Lloyd et al. (2018)'s study, students who expressed an interest in STEM were typically high achieving, and just over 90% of their parents had aspirations for them to attend university—although this was proportionally higher for sons than for daughters. Even when parents created a supportive environment, there was little evidence indicating that girls were encouraged to pursue STEM. The research also highlighted the complexity and importance of parental influences on student aspirations.

For the influence of peers, the result of Micari et al. (2016) study indicated that academic-preparedness diversity was mostly associated with positive learning outcomes. They found that academically less-prepared students got greater benefits, and those less-prepared students performed better when they were not alone in a group of highly prepared students.

The role of school in STEM learning

The factors within the school learning environment include teachers' profile, experience, beliefs and expectations, curricula, learning materials and resources, teaching strategies and student teacher interactions, assessment practices and the overall school environment (Chavatzia, 2017). Among the offering of definitions and conceptions of STEM, putting STEM education into practice requires teachers to have a different knowledge base than that of subject teachers, to enable them to play an important role in providing students with the integrated learning opportunities with STEM. Participation in advanced STEM coursework at the secondary level increases female students' likelihood of pursuing a STEM pathway in postsecondary education (Hinojosa et al., 2016).

The role of society in STEM learning

STEM permeates the modern world. The jobs people do, the foods they eat, the vehicles in which they travel, the information they receive, the medicines they take, and many other facets of modern life are constantly changing as STEM knowledge steadily accumulates (Olson and Labov, 2014). Social and cultural norms are related to gender equality, and gender stereotypes in the media (Chavatzia, 2017). Lee et al. (2018) identified students' social perspectives for their pursuit of a STEM career, to help people, to interact with others with 21st century ideas, and to impact the world.

Fig. 1 near here shows the recommendation by So and Chiu's (2020) in their policy research at different levels of individual, family, school and society of the STEM learning ecosystem. For the individual level, there is need to make available learning opportunities and narrow the gender gap. For the family level, it is recommended to enhance parent education on students' study and career choices. For the school level, it is essential to articulate STEM learning progression across key stages and integrate STEM career understanding into school curriculum. For the society level, it is indispensable to improve quality of STEM education and highlight STEM contribution to the contemporary society.

Fig. 1 The recommendation at the various levels of the STEM Learning Ecosystem. Source: So and Chiu, 2020, p. 63.

Students' STEM aspirations

A learning ecosystem drives the unique contributions of each different setting to offer STEM learning for children (Traphagen and Traill, 2014). Unfortunately, these various settings are in different stages of evolution, and people from one setting often do not know the people or organizations from other sectors. How to motivate and engage the people from different settings and work with others as part of a unified endeavor is not an easy task; it needs some mutual understanding of the roles of each sector in the STEM learning ecosystem. So and Chiu (2020) argued that understanding students' intention to pursue a STEM career is required for strategy formulation to nurture young people with the necessary skills, education and experience to engage as STEM professionals.

Archer et al. (2014) explained why aspirations are an interesting and important focus for research, and young people's aspirations remain an enduring focus of education policy interest and concern. Their research analysis indicated patterns of association between particular sources of influence and types of career aspiration. For example, aspirations for sports and the arts were overwhelmingly related to children's out-of-school activities. Middle-class children were more likely to cite family capital in relation to professional careers in the fields of medicine and teaching. Working-class students were much less likely to aspire to follow in a family member's footsteps or to develop their aspirations through an out-of-school hobby/activity. The researcher criticized that this is an unfair social enterprise that only the privileged few are likely to attain.

However, the reasons why students not choosing STEM careers may due to common misunderstandings that STEM is a difficult, uncreative, passionless and socially isolated enterprise (Masnick et al., 2010). Students' lack of interest or aspirations in STEM careers is a concern worldwide (The White House, 2018).

Lee et al. (2018) indicated that for those who selected STEM careers for their future employment, the perspectives they held that motivated their STEM career aspirations were mainly from personal and societal perspectives. Students with a personal context usually have positive emotions, personal development, and developing tools for the job. Students whose perspectives best reflected a societal context were helping people, interacting with others, and impacting the world.

On top of Mau and Li's (2018) research result that race, gender, socioeconomic status, mathematics interest, and science self-efficacy were the most important predictors of STEM career aspirations, So and Chiu (2020) suggested building STEM capital to bridge the socio-economic status gap as more informal STEM activities are one of the significant predictors of students' STEM aspiration.

Principles to support STEM education across various settings

Olson and Labov (2014) indicated that the STEM learning system is remarkably diverse, and all parts of the system have something to contribute to STEM learning. The challenge is to mesh these contributions synergistically while adapting models that have worked well in one place to the culture, governance, and idiosyncrasies in other settings. In other words, the goal is to create an actual integrated system for teaching and learning wherever learning occurs, both in and outside of school, rather than a set of uncoordinated activities.

Penuel et al. (2014) reviewed the literature on cross-setting learning, and reported on several design principles they identified which are useful for STEM learning: (1) Draw on values and practices from the various settings and identify practices in one setting that can be used as a resource to support learning in others. (2) Structure partnerships to embrace the goals of all stakeholders. (3) Engage participants in building stories, imaginative worlds, and artifacts that span contexts and that facilitate meaning-making across contexts. (4) Help students identify learning opportunities to contribute to authentic endeavors. (5) Use brokering purposefully, for example, preparing educators and parents to play roles as brokers to facilitate movement across settings.

The guide to STEM Community Engagement provided schools, districts, and local community organizations with self-guided tools to engage a broad community of stakeholders in sustainable education innovation. It suggested five design principles to drive the work, namely: (1) Equitable; (2) Scalable & sustainable; (3) Innovative, (4) STEM-focused; and (5) collaborative.

These principles aim to make students the center of our communal efforts across settings. Although Tytler et al.'s (2018) discussion of the community partnerships is focusing on sustainability education, the benefits they mentioned are useful and can be translated to STEM education, including curriculum links, community network formation, volunteering in STEM work, students' career and attitude development.

The above three principles show there are different ways to support STEM learning. Based on the work by Morrison and Fisher (2019) on measurement in STEM learning ecosystems that build on expectations have already been articulated concerning progressions in the quality of partnerships, collaborations, and outcomes. We propose a summary of the principles to support STEM learning across sectors as follows:

1. Connect parents and/or teachers with links to the curriculum and daily life for a sustainable effect
2. Address contributions across collaborators to achieve one's goals and to share best practices
3. Facilitate meaningful learning opportunities with innovative and authentic tasks that are transferrable across contexts
4. Focus on students' attitudes and career development as outcomes

Various practices with community engagement in STEM education

There are different practices of community engagement in STEM education based on the various principles. Most of them are also practices used in other areas but with special focuses on STEM learning. They are service learning, fair/competition, information websites, network websites, science museums, outreach programs and family engagement in STEM education.

STEM service learning

Preece (2017) claimed that service is a largely philanthropic endeavor. The conceptual movement is from one of “service” to the community to one of “engaged scholarship” as an integral element of teaching, research and knowledge production, embracing the interdisciplinary, problem-based and experiential concepts. Service-learning is also a form of teaching and learning that combines subject learning with civic engagement. In the “Taking Social Responsibilities” project, learners put knowledge and skills learned in science class to practical use while making an active contribution to their communities.

The study conducted by Jensen and Burr (2006) found that service-learning activities can serve as a tool for engaging some students who would not normally respond to traditional methods of teaching. Moreover, results from Newman et al. (2015) study showed gains in three areas of measures of academic achievement and academic engagement, civic responsibility and resiliency.

Hayford et al. (2014) found that improving STEM literacy is also a focal point of STEM education and has been explicitly linked to service learning activities. Hayford et al. (2015) postulated that components of service-learning, including the deliverables and reflections, are examples of fundamental STEM literacy which can be assessed for STEM learning outcomes.

Moreover, the study (Daniel and Mishra, 2017) measured student affective, behavior, and content (ABC), as well as global awareness outcomes after participating in a STEM-based international service-learning course indicated positive improvements in affective outcomes and significant gains in civic awareness. The differences in behavior based on class of student, the specific content gains related to the service-learning activities. There were global awareness gains for all students and differential impacts on retention in STEM-related fields.

STEM fair/competition

There has been increasing student participation in science fairs, robotics competitions, computing contests and other STEM competitions every year. And research conducted on the relationship between student competition participation and their learning are reporting positive effect. For instance, the research on students participated in the RoboCupJunior, one of the World Championship, reported the effectiveness of its practice for enhancing learning of STEM content and skills for innovation and creativity among participating students (Eguchi, 2016). The result from 4th to 12th graders by a STEM assessment before and after the Robofest competition showed significant improvement in mathematics scores (Chung et al., 2014).

Miller et al. (2017) study using data from the “Outreach Programs and Science Career Intentions” survey reported that competitions are an effective way to foster career interest in specific STEM careers. Their result revealed that, first, students who participated in STEM competitions are more likely to express interest in a STEM-related career. Second, the relationship between competition participation and interest in a STEM career appears to be domain specific. Third, the impact of competition participation on pursuit of a STEM career is three times stronger when students compete in more than one competition.

So et al. (2017) adopted a researcher-generated framework to analyze STEM activities demonstrated in primary students’ projects in an annual STEM event, found that the framework does not only provided better understanding of assessment of students’ performance of STEM integration in projects, it also offered baseline information and suggestions for further research and instructional efforts in the planning and implementation of the future development of quality STEM education at the primary school level.

STEM information website

Nakamura et al. (2018) considered that knowledge structure of STEM is huge and complicated, that visualization of knowledge structure is very useful for learning STEM. The STEM@HKUST not only seeks to be a one-stop shop of information on STEM-related events and competitions, but also showcases original videos produced by the university faculty, staff and students which explain everyday conundrums in a lively manner. Students can suggest topics or experiments they want to watch, while secondary school teachers with queries on STEM-related topics are also welcomed to raise questions through the website. Wabisabi learning also provided a list of useful websites with contributions for various STEM professionals to facilitate STEM learning including how to begin preparing students for these swiftly approaching occupations. Creating STEM classroom opportunities that excite and inspire our children is a great place to start.

STEM network website

National Lab Network is an initiative that matches teachers and students with members of the STEM community. It began as “National Lab Day” by connecting schools with educational, scientific, and engineering organizations nationwide to work together on projects related to STEM. The original one-day event has evolved into an ongoing, collaborative network of schools and community leaders. Teachers can request community support by posting information about their STEM classroom projects. They were

matched with local STEM volunteers including university STEM students and faculty, scientists, engineers, professionals, and other community members involved in STEM. Projects ranged from helping students with science fairs to coordinating or hosting field trips to mentoring a student with STEM work.

Science museum visit

Given the growing interest in supporting STEM learning opportunities for youth, museums and other designed settings offer extensive experience and expertise as resources to support youth and communities in deepening and expanding such opportunities (Chi et al., 2015). The informal science learning environments such as science museums might provide valuable spaces within which to engage visitors (Archer et al., 2016). They explored the experiences of socially disadvantaged families in a science museum visit and found that families' experiences could be characterised into three discourses, as "disorientating", "fun" or "meaningful" visits. Analysis identified the families' experiences, and the likelihood of deriving science learning from the visit were shaped through interactions of habitus and capital.

STEM-rich learning environments like science museums which expose children to STEM can spark and nurture children's interest in and enthusiasm for STEM (Traphagen and Traill, 2014). The study conducted by Haden et al. (2014) facilitated an educational program in a museum. Prior to the exhibition, the families were randomly assigned to conditions that varied in terms of the instructions about a key engineering principle and elaborative question-asking they received. The participants were then observed during the exhibition. Conversation instruction resulted in adults asking double the number of Wh-questions compared to families who did not receive the instruction. The study found that the instruction was effective in terms of promoting family conversations and children's learning about STEM.

STEM outreach activities

Vennix et al. (2018) investigated outreach activities developed by STEM-based companies or universities with an aim to inform students about and motivate them for a career in STEM by connecting the work-context with school-science. Their research investigated students' perceptions with the outreach learning environment, perceived need-fulfilment, self-reported motivation and attitudes toward STEM. The findings show that outreach learning environments created opportunities to increase students' motivation in STEM and attitude toward STEM, but the impact varied according to the particular characteristics of the activities. Moreover, the effectiveness of STEM outreach program studied by Dubetz and Wilson (2013) noted the increase in scientific familiarity that encouraged girls to consider related careers and helped develop better informed scientific citizens.

Another study on paired peer learning through engineering education outreach by Fogg-Rogers et al. (2016) observed that the activities are having multiple benefits to both students, teachers and engineers. First, increased school children's interest and engagement with science and engineering. Second, provided teachers with expert contributions to engineering subject knowledge. And third, developing engineers with professional generic skills of communication and teamwork.

The scientific and technological community has a vital role to play in reaching out to make education reform efforts and encourage young people to study and pursue careers in STEM (Kesidou and Koppal, 2004). Yet, it would be better to focus on identifying resources and strategies that can be used to enrich outreach efforts that aim to supplement or enhance STEM content for students. The three recommendations are: (1) align outreach efforts to relevant content standards, that is, close to the curriculum; (2) pay attention to what students are thinking, that is to have continuous evaluation of students' achievement; and (3) take advantage of instructional strategies that work, that is to have association with teaching and learning in classrooms.

Family engagement in STEM

Jackson and Harbison (2014) showed that family involvement in their child's education has a greater impact on the child's learning than variables such as social class, level of parental education or parental income. In a study about young children and science (Silander et al., 2018), it was found that 99% of parents wanted to be involved in their children's education, but they did not understand the role they can play. For instance, they did not know that there was no need to have the right answer nor communicate the information appropriately; rather, parents were there to support their children's exploration.

It is suggested by the family engagement, A STEM NEXT Project Opportunity fund initiative, to empower parents to support their children's participation and persistence in STEM. Family engagement can start with listening, learning, and building relationships with families. Parents should be empowered with research and resources. They do not need to be the experts or to have the answers, particularly in relation to STEM; rather, it is their encouragement that matters. Providing professional development to team members for impactful family engagement to better engage parents and sustain further exploration at home is also one key practice for successful family engagement. Last but not least, evaluating the impact with a brief survey instrument using social media and through online platforms is recommended. During the whole process, it is also important to prioritize access and inclusion to consider who benefits and who is left out and left behind.

The effect of parent engagement in children's STEM learning is still under investigation. The meta-analysis of the literature on parental engagement with children's STEM education (Milner-Bolotin and Marotto, 2018) reported the followings themes: (1) The challenges of supporting parents with children's STEM education; (2) STEM education as a bridge between school and family;

(3) STEM education as a gateway for children's future economic success; (4) STEM education as a vehicle for promoting student communication skills; and, (5) the role of hands-on inquiry-based activities in enhancing student engagement.

Recommendations

Based on the above discussions of STEM learning ecosystems with the roles of individuals, families, schools and the society in STEM learning; the importance of students' STEM aspiration to bridge the gap between STEM education and the required work force for the growth of innovation and technology in the contemporary world; and the significance of engaging communities in STEM education and the various practices with community engagement in STEM education, the following recommendations are proposed for continuous and future development to engage community stakeholders in students' STEM learning. These include establishing STEM professional-school collaboration, developing STEM communities of practice, and highlighting STEM professional contributions to society.

Establishing STEM professional-school collaboration

There are limited practical ways to help students understand the nature of science careers. Wyss, Heulskamp, and Siebert (2012) suggested providing school students with accurate information about STEM careers to enable them to make more knowledgeable choices about courses of study and career paths. They investigated the use of video interviews with STEM professionals to better inform students about STEM career possibilities, and got compelling evidence of implementing video interviews to arouse students' interest in pursuing STEM careers.

Watters and Diezmann's (2013) study established and implemented partnerships with industry experts in an attempt to stimulate youth's interest in the contemporary world of science. The formation of relationships and partnerships induced students' high degree of autonomy and sense of responsibility, which are important attitudes toward STEM.

El-Deghaidy and Mansour (2015) conducted a STEM partnership-based Professional Development program, in which participating teachers suggested that a direct dialogue between science teachers, mathematics teachers, scientists, and engineers about STEM applications and activities is essential for promoting STEM education in schools. This provides insights for teachers and scientists to work together to assist students in making learning more meaningful.

Cheng and So (2020) reported an example of the total integration of STEM learning which provided opportunities for students to engage in simulation activities as water engineers. It began with some basic information about the daily tasks of water engineers, followed by students' mimicking water engineering to solve the problem of a sustainable supply of energy for reservoirs by designing a mini floating solar power system to capture renewable energy from the sun. At the same time, students could work on investigating problems, such as the effect on algal growth arising from the use of the solar panels on reservoirs. The design of the STEM learning scaled up from simulation to real situations to solve an authentic problem encountered by the STEM professional.

Developing STEM communities of practice (STEM CoPs)

STEM education for our young generation is more than just about knowledge, skills and thinking processes; it is a matter of literacy that all school leavers should acquire (So and Chiu, 2020). Scientists helped us better understand the behaviors of the natural and physical world, based on scientific principles, engineers solved problems and created things that had never existed before. Mackie (2019) proposed a high-functioning STEM community which is youth-focused, action-oriented, hands-on, and adult-coached. It is a means for the STEM community to not only transfer relevant knowledge, best practices, successful practicalities, and expected social norms, but also to share, embed, and make easily reachable best practices and lessons learned from the STEM stakeholders in the community. An example is the community of STEM NOLA which leveraged what is believed to be the best from that classic model, with one group of paid college students to help with the group of volunteer STEM professionals, retired professionals and community elders.

The Community of Practice (CoP) was defined by Wenger et al. (2002) as "Groups of people who share a concern, a set of problems, a passion about a topic and who deepen their knowledge and expertise in that area by interacting on an ongoing basis" (p. 4). STEM education through a Community of Practice (STEM CoP) can also provide opportunities for teachers and students to learn the common and unique practices of STEM professionals in the community and to identify key learning outcomes necessary to achieve what are grounded in common shared practices in real-world contexts. An example of a STEM CoP is the community effort in plastic waste recycling (Chow et al., 2016) focusing on the plastic waste problem in a city. The common practices are the practical experiences of developing, testing, using and maintenance of bins for plastic recycling. This is followed by interaction with the community for innovative ideas and strategies for recycling plastic "waste".

Highlighting STEM professional contribution to the society

Due to the rapid growth in innovation and technology, the future jobs and occupations taken by today's learners may not exist as of today; furthermore, many of these future jobs are probably STEM-related. Yet, without even mentioning future occupations,

students nowadays do not even know the existing STEM occupations serving our community. How to excite and inspire our children and prepare students for the demand of the innovation and technology growth and swiftly approaching STEM occupations in our community is a timely question.

One of the directions of STEM education should be closely related to the daily operation and development of the local community with various government services to serve the people living in its jurisdiction. To strengthen this linkage, we should consider stepping up and pitching the public education programs from various STEM-related Government departments toward our young generation (So and Chiu, 2020). The services, ranging from food packaging and safety, manufacturing of disinfecting cleaners during pandemics, architecture for city planning and road construction, drainage systems for sewerage treatment and flood prevention, firefighting and calamities protection, water and energy supply, could be made available for students to relate their STEM learning to everyday life, and to spark their STEM interest.

The mass media are also a key channel to promote STEM. Any promotion messages and programs can benefit students and their parents, to have some impact on steering them toward the study and career choice of a STEM profession. This will eventually contribute to the community goal of economic development through science and technology. A television program “Our Scientist” produced by Radio Television Hong Kong not only aroused public concern for and awareness of the importance of STEM contributions to society, but was also successful in revealing scientists’ non-nerdy images as a person (So and Chiu, 2020). The program was successful in demonstrating that, other than scientific work, the male environmental hydraulics professional being interviewed also excels in ballet and table-tennis.

Concluding remarks - a look into the future

Reflecting on the development of STEM education in the United States during the past few decades, the NSTA Board of Directors adopted in February 2020 a new Position Statement on STEM Education Teaching and Learning indicating that STEM education has been evolving from a convenient clustering of four overlapping disciplines toward a more cohesive knowledge base and skill set critical for the 21st century (<https://www.nsta.org/about/positions/stem.aspx>). New goals for a Modern STEM education that will promote not only skills such as critical thinking, problem solving, higher-order thinking, design, and inference, but also behavioral competencies such as perseverance, adaptability, cooperation, organization, and responsibility are advocated. A strong foundation in language and creative arts, together with the ability to fully comprehend global issues were also emphasized. With a number of recommendations, STEM education leaders are advised to continue to broaden and deepen the scope of STEM education and to involve the entire community to play a critical role in shaping the STEM vision and supporting its implementation through active participation. It is worth noting that the emphasis on new goals of STEM education and some additional competencies as mentioned above is in line with a recent global trend concerning education for the future and the development of 21st Century literacy/competencies (Howard et al., 2019; OECD, 2018).

Increasingly, in the past two decades, educators and policy makers around the world have come to realize the importance and potential impacts of the volatile, uncertain, complex, and ambiguous nature of the 21st Century on the future development of citizens, the human race, and our entire planet. Taking a more holistic and systemic way of thinking, a number of educators, research projects, and international organizations have reflected on the shortcomings and limitations of our past and current education systems and practices, while offering a range of suggestions for the transformation to a better global future education. Some earlier works in this direction have been extensively reviewed by a report supported by the World Innovation Summit for Education (Liu, 2015), while results of more recent studies, conference reports and so on continue to appear (GELP, 2017, 2019; Luksha et al., 2018; OECD, 2018, 2019).

For instance, based on a series of previous studies, the OECD proposed the Learning Framework 2030 which offers a vision and some principles for the future of education (OECD, 2018). This framework emphasizes a commitment to helping every learner develop as a whole person, fulfill his or her potential and help shape a shared future built on the well-being of individuals, communities and the planet. It also outlines a number of underpinning principles for the future of education systems, including the need for learner agency in terms of navigating through a complex and uncertain world, the need for a broad set of knowledge, skills, attitudes and values in action, and especially a new set of what they called “Transformative Competencies” that together address the growing need for young people to be able to create new value, to reconcile tensions and dilemmas, and to take responsibility. To ensure that the new learning framework is actionable, the OECD Learning Framework 2030 also includes some design principles for moving toward an eco-systemic change.

Besides the OECD (2018), GELP (2017, 2019), Schleicher (2018), Cook (2019), and many others have made efforts along similar lines. Without going into further details, suffice to say that as an integral part of the education system, STEM education, especially with community engagement, has significant new roles to play in the future. The concepts and practices briefly introduced in this article can be integrated into efforts to reform education to better equip future generations to meet the challenges posed not only by issues of technological and economic advancement, but also equity, social justice, environmental degradation, climate change and so on, and to help shape a shared future built on the well-being of individuals, communities and the planet. There are a significant number of partnerships and programs in place that bring together schools, industry and universities to support STEM engagement. However, more needs to be done to improve the coordination and reach of these arrangements, particularly for under-represented students, and to identify best practices (Education Council, 2015). Of course, developing a STEM community is time-intensive, challenging, and demands dedication, but it can be done.

What is informal STEM learning?

Individuals learn science, technology, engineering and mathematics (STEM) across a wide range of contexts, settings and experiences. While some STEM learning takes place within the formal classroom, much of it happens outside of school through the process of informal STEM learning (National Research Council [NRC], 2009; National Academies of Sciences, Engineering and Medicine, 2018; Rennie, 2007). Although the term “informal” may suggest a lack of seriousness or rigor, in reality it refers to the context in which these learning experiences take place. Informal STEM learning represents a range of learning opportunities that happen beyond the classroom or other formal schooling environments such as through printed media, the internet, at museums and in afterschool programs (Crane, 1994; NRC, 2009, 2015; Rennie, 2014; Storksdieck et al., 2016). Because it takes place outside of the formal classroom, informal STEM learning is usually voluntary, self-motivated, and guided by the learners’ needs and interests rather than by curriculum or standards (NRC, 2009). In addition, whereas learning in the classroom is usually an individual endeavor, learning in informal STEM settings is often socially constructed as families or groups of friends make sense of informal STEM experiences at museums or related institutions and during everyday activities at home (Rennie et al., 2003).

Although informal STEM learning and formal school learning are often presented as dichotomous entities, they can be conceptualized as a continuum of learning opportunities defined by a range of characteristics including choice, facilitation, purpose and assessment. Formal schooling, for example, falls at one end of the spectrum and is characterized as highly structured, designed to address a specific curriculum, provides limited choice and incorporates assessments that determine whether or not a learner has adequately met a particular objective. Opportunities to learn STEM in everyday settings such as watching a science documentary at home fall at the other end of the spectrum in that they are not aligned with any particular curriculum or learning outcomes, offer high levels of choice and have limited structure and facilitation strategies. However, many other informal STEM learning experiences fall somewhere in between these extremes. Field trips, for instance, often take place in informal settings such as museums or zoos, and may offer varied levels of choice for learners, but they also can be highly structured and facilitated, may incorporate assessments that count toward a student’s grade and typically are aligned with a curriculum or have an intended and specific learning outcome (Behrendt and Franklin, 2014; DeWitt and Storksdieck, 2008; Storksdieck, 2006).

In light of the inherent complexity of categorizing informal STEM learning experiences based on the above range of characteristics, the Committee on Learning Science in Informal Environments (NRC, 2009) chose to organize its analysis based on the places in which informal STEM learning typically occurs, focusing on the following three categories of venues: everyday learning, designed environments and programs.

Everyday learning represents the day-to-day types of activities where individuals engage with STEM, either intentionally or incidentally (NRC, 2009, 2015; Tal and Dierking, 2014). In these settings, STEM learning is not necessarily an explicit or intended outcome but may result as individuals encounter STEM content, practices or ways of thinking. Generally, everyday environments have a low degree of structure and facilitation. Examples of everyday environments include (but are not limited to) engaging with STEM oriented media or the internet, playing at the park and family activities where science is encountered (e.g., cooking, gardening, family discussions) (NRC, 2009, 2015; Storksdieck and Falk, 2020).

Designed environments are intentionally created for specific STEM learning outcomes and commonly have collections of artifacts, materials or animals. As compared to everyday settings for learning, these environments may have a higher degree of structure and facilitation but are more sporadic in nature than programs. Learners usually have significant choice in designed settings to select what exhibits and experiences to attend and for how long they want to engage. Examples of designed settings including museums, science centers, nature centers, zoos and aquariums (NRC, 2009, 2015; Falk and Storksdieck, 2005).

Programs are also designed for a specific outcome and like designed environments, tend to have a higher degree of structure and facilitation. However, they are generally a more consistent (likely to occur over time) learning opportunity as compared to designed settings as well as more aligned with a specific curricular goal. In some cases, programs are offered through a designed environment such as a summer science camp program offered at a local zoo. Generally, programs tend to focus on a prescribed audience or group of learners such as an afterschool program targeting young learners, or a volunteer group that caters to adult learners. Examples of STEM programs for youth include field trips, science clubs, afterschool programs, and robotics programs, while adults may participate in hobby clubs, citizen science programs or learning vacations. In addition there are specialized STEM programs such as teacher professional development opportunities in non-school settings (e.g., museums) (NRC, 2009, 2015).

Learning in informal STEM environments

Significant STEM learning can and does take place in each of the venues described above; however, it can be challenging to document and measure the extent of learning outcomes due to the unique, self-directed and highly personal nature of such experiences which make them difficult to evaluate with standard measures (Allen and Peterman, 2019). Consequently, most informal STEM learning research to date has been limited in both duration and scope, designed to document the results of short-term experiences such as the learning outcomes from a single designed environment visit (e.g., science center) or participation in a program (e.g., field trip), while comparatively little research has addressed the learning that takes place in unstructured everyday environments or the long-term outcomes of participation (Allen et al., 2019; Dabney et al., 2012; NRC, 2015; Young et al., 2017).

Substantial research has examined informal STEM learning in designed spaces such as museums, science centers, zoos and aquariums, and these studies have provided considerable evidence of learning, even over the span of just a single visit (NRC, 2009). Visitors of all ages often learn STEM content and increase their scientific understandings based on the exhibits and activities they engage in, as evidenced by significant factual recall even several months after the experience (Anderson et al., 2007; Falk and Storksdieck, 2005, 2010; Jones, 2005; Korn, 2006; Medved and Oatley, 2000). In addition, researchers have demonstrated that many visitors engage in scientific reasoning behaviors such as meaning making and explanation of scientific principles as they explore and make sense of experiences, particularly interactive exhibits, in designed settings (e.g., Allen, 2007; Goldowsky, 2002; Randol, 2005; Zimmerman et al., 2010). Others have found that these learning outcomes are not universal, but in fact are strongly influenced by visitor goals and motivations. For example, Packer and Ballantyne (2002) identified five categories of visitor goals reflecting peoples' stated reasons for visiting educational leisure institutions such as museums and interpretive sites: (1) passive enjoyment; (2) learning and discovery; (3) personal self-fulfillment; (4) restoration; and (5) social contact. Their research showed that only visitors with learning and discovery goals exhibited significant learning and interest development outcomes. Using a similar visitor motivation taxonomy, Falk et al. (2008) found that motivations accounted for about a quarter of the conservation-related attitudes reported by zoo and aquarium visitors, further suggesting that visitor goals and motivations may be strong drivers for what participants ultimately learn in designed settings.

Out-of-school STEM programs (including afterschool, summer camps, clubs, and field trips) also have been extensively studied to better understand how they may benefit STEM learning for participating youth. Such programs provide expanded content-rich learning opportunities, often engaging students in rigorous, purposeful activities that feature hands-on engagement that inspire inquiry, reasoning, and problem-solving (Afterschool Alliance, 2014; NRC, 2015). In addition, out-of-school STEM activities may allow students to meet STEM professionals and learn about STEM careers (Bevan and Michalchik, 2013; Fadigan and Hamrich, 2004), and can help learners to expand their identities as achievers in the context of STEM as they are actively involved in producing scientific knowledge and understanding (Barton and Tan, 2010). Despite the strong potential for out-of-school STEM programs to provide positive benefits to participants, it has been difficult for researchers and evaluators to document significant changes in outcomes for youth as a result of participation in these programs (NRC, 2009). This may be due in part to a measurement limitation called the ceiling effect which can occur when a large proportion of subjects begin a study with very high scores on the measured variable(s), such that participation in an educational experience cannot yield significant gains among these learners (Judson, 2012; Staus et al., 2021b). This effect is often attributed to the biased nature of participation in informal STEM programs; that is, youth generally choose to participate because they are already interested in and potentially knowledgeable about the content area. Despite this limitation, several recent large-scale research and evaluation projects suggest that in the short term such programs can lead to increases in STEM interest, engagement, identity, career interest, career knowledge, and critical thinking (Allen et al., 2019; Riedinger and McGinnis, 2017; Young et al., 2017).

The role of informal STEM learning in the larger STEM ecosystem

Although short-term learning outcomes are important and worthwhile, evidence suggests that the principal benefits of informal STEM experiences are long-term transformations in learners as they pursue a "cascade" of experiences cumulatively across a diversity of physical and social contexts including school, home, museums, media, and science programs (Bronfenbrenner, 1979; National Academies of Sciences Engineering and Medicine, 2018a; NRC, 2009, 2010). For example, an individual's understanding of astronomy might represent the cumulative experiences of completing a classroom assignment about the planets, reading a book about cosmology by Stephen Hawking, visiting an air and space museum, watching relevant television programs, stargazing

through a telescope, and joining an astronomy club. For the individual, each of these experiences, most of them in the realm of informal STEM learning, combine to create a personal understanding of astronomy.

While fictitious, the above example of astronomy learning appears to be an accurate representation of the importance of informal STEM learning experiences in the learning of STEM more broadly. Given that most people spend only a small fraction of their life in school, informal STEM learning experiences such as those described above appear to be particularly important in contributing to people's STEM understandings over time (Falk and Dierking, 2010; Sosniak, 2001). Because virtually everyone engages in informal STEM learning activities nearly every day, from reading a news article about science to tending a garden, people accumulate STEM knowledge throughout their lifetimes, not just the years they are in school.

Accordingly, scholars have begun examining STEM learning from an ecological perspective, in which the educational "ecosystem" is conceptualized as a set of environments, both physical and virtual, in- and out-of-school, that provide people of all ages and backgrounds with opportunities to learn (Barron, 2010; Jackson, 2013; Traphagen and Traill, 2014). Within the larger ecosystem, learners construct unique STEM learning pathways guided by personal goals and interests and supported by a variety of sociocultural and physical factors including activities, resources, and relationships that the learner can engage with to support their personal interests and learning goals (Barron, 2006, 2010; Corin et al., 2017; Crowley et al., 2015; Shaby et al., 2021).

These studies have revealed that informal STEM learning experiences, particularly during adolescence, are important and may be critical for the development of enduring STEM interest over time. For example, Crowley et al. (2015) conducted retrospective life-history interviews with adult scientists and engineers inquiring about their early disciplinary interests and the ways those interests were developed and supported throughout their lives. They found that individual interest in science often emerged before high school and was supported by ample opportunities to learn in informal STEM learning settings such as enrolling in STEM programs, visiting informal learning settings, and/or pursuing information in books or online. Similarly, Hecht et al. (2019) explored retrospective life histories of naturalists to examine experiences that they recalled supporting their interest development in the natural world and found that persistent exposure to nature throughout their childhoods was critical for their long-term commitment to engagement with nature. In a large-scale survey of nearly 7000 nationally representative university students in the US, Dabney et al. (2012) found that students who participated in either structured or unstructured informal STEM learning activities were up to 1.5 times more likely to report a career interest in a STEM discipline. More recently, a longitudinal study of adolescents aged 11 to 13 indicated that more frequent participation in out-of-school STEM activities was a strong predictor of persistent STEM interest over time (Staus et al., 2020).

In addition to the importance of informal STEM learning early in life, there is growing evidence that suggests these experiences support the life-long learning trajectories of adults. A recent study of astronomy and birding hobbyists indicated that informal STEM learning organizations such as museums, universities and clubs were instrumental in connecting adult learners with relevant opportunities within the STEM learning ecosystem (Corin et al., 2017; Storksdieck et al., 2012; Yocco et al., 2012). As the hobbyists became more skilled and knowledgeable, such organizations then acted as catalysts to facilitate access to other elements of the STEM learning ecosystem such as hobby-related conferences or formal learning institutions to further develop their hobby. Similarly, citizen science programs aimed at adult participants are emerging as important informal STEM learning activities that facilitate both increased science literacy and the collection of highly rigorous, longitudinal data for researchers (He et al., 2019). However, although citizen science projects are rapidly increasing in number, the effect of such projects on adults' STEM learning outcomes and trajectories are not yet well documented (Brossard et al., 2005; National Academies of Sciences, Engineering, and Medicine, 2018b).

Broadening participation in informal STEM learning

Given the importance of informal STEM learning experiences for triggering and sustaining interest in STEM and providing valuable opportunities for individuals of any age to engage with and learn about STEM, there is growing interest in broadening participation in informal STEM learning, particularly for groups who have been historically under-represented or marginalized in STEM fields (DeWitt and Archer, 2017). In general, learning is maximized when it is supported and reinforced through participation in multiple experiences within the STEM learning ecosystem (DeWitt and Storksdieck, 2008; NRC, 2015). However, while a STEM learning ecosystem may contain a large variety of informal STEM learning experiences and resources, such opportunities may not be equally accessible to all learners. In fact, informal STEM learning resources are often disconnected and uncoordinated in such a way that learners may have difficulty finding "the next thing" that supports their particular interest (Bell, 2013). The disjointed nature of resources within learning ecosystems is particularly problematic for individuals from under-represented or disempowered groups (DeWitt and Archer, 2017). For example, a recent study of STEM interest and participation of adolescents in a diverse low-income neighborhood in Portland, Oregon, USA, found that the disconnected nature of the informal STEM opportunities in the learning ecosystem proved to be a significant constraint to persistence in STEM interests and activities for some youth whose families had difficulty identifying and connecting to relevant resources (Shaby et al., 2021). A major goal in the future will be to develop effective supports to enhance navigation of STEM ecosystems, perhaps by utilizing brokers who can help learners connect to experiences of interest (Allen et al., 2020; Ching et al., 2016).

The challenge of connecting learning settings appears to be widespread across learning ecosystems worldwide. A recent landscape study of UK science learning resources (Falk et al., 2015), revealed that the science education community was highly interconnected within sectors, but only moderately interconnected and collaborative between sectors (e.g., science centers, schools, hobby clubs). In particular, the school sector emerged as a major outlier that rarely connected or collaborated with informal science

learning sectors or even other schools, making it difficult for learners to identify and connect with additional learning opportunities related to their science interests. [Shaby et al. \(2021\)](#) also noted a lack of collaboration between formal and informal STEM providers in the learning ecosystem and suggested that successful ecosystem coordination requires that all STEM providers in an ecosystem commit to on-going and continuous communication among and between themselves, ensuring that opportunities and options are clearly signposted for youth and their families.

Recently, the *Connected Science Learning: Linking In-School and Out-of-School STEM Learning* (CSL) project – a collaborative effort between the National Science Teaching Association (NSTA) and the Association of Science and Technology Centers (ASTC) – addressed this issue by creating a scholarly journal designed to connect the work of STEM education practitioners with each other and with those conducting research in the area of informal STEM learning. An evaluation of the project showed that the journal provided great value to the field by featuring successful partnerships and models that create connections across the learning ecosystem. Additionally, STEM education professionals noted that the CSL journal translated research to practical applications, offered a mechanism for connecting STEM education practitioners, and provided an outlet where out-of-school education practitioners could write about and share details of their work ([Riedinger, 2017](#)). Efforts such as this have the potential to create more connected, functional STEM ecosystems for more learners.

But helping more people identify and connect with informal STEM learning resources does not address an even more pressing issue, which is the fact that some opportunities are not equally available to all learners due to social or cultural barriers to participation. Despite the perception that informal STEM learning by its nature is equally available to all, there is some evidence that institutions such as museums and science centers, rather than being easily accessible STEM resources for their communities, may actually exclude low-income and/or minoritized ethnic groups through their culture and practices ([Dawson, 2014a, 2014b, 2019](#)). For example, many institutions provide interpretive materials in only the dominant language, making it difficult for learners who speak different languages to understand and fully participate in the STEM activities ([Rahm and Ash, 2008](#)). In addition, many exhibits require an existing understanding of scientific terms and concepts that may exclude some visitors. The high financial cost of admission also may deter many potential visitors with limited incomes. These and other institutional practices reinforce social disadvantages such that minoritized visitors experience informal STEM learning institutions as unwelcoming places where their knowledge and practices are not valued or respected ([Young, 2000](#)). Clearly there is work to be done toward making informal STEM learning experiences inclusive to meet the needs of a diverse range of STEM learners.

Conclusions and future directions

Informal environments can provide rich opportunities for learning about STEM. Because virtually everyone participates in informal STEM learning in the course of daily life, from looking up health information on the internet to caring for a pet, informal STEM learning environments have the potential to support a broad range of learning experiences for any individual, of any age or background, with an interest in STEM topics or activities. Informal STEM learning experiences can stimulate interest in STEM, build STEM knowledge and skills, and support pathways of life-long STEM learning. However, there remain a number of areas for further exploration to provide more detailed understandings of learning processes and outcomes, as well as how to better support more learners in their STEM investigations.

Supporting equity and inclusion for all learners

Due to the often significant barriers to identifying and accessing informal STEM learning resources for some learners, especially members of low-income and minoritized communities, in the future informal STEM learning providers must better account for the fact that learners are not homogeneous groups but are rather comprised of members of numerous different socio-cultural groups whose science explorations are shaped by their unique backgrounds and lived experiences reflecting a diversity of science perspectives ([NRC, 2009](#)). In particular, there must be a rethinking of designed spaces and programs in order to provide more equitable and inclusive opportunities for all to participate in informal STEM learning experiences and environments ([Dawson, 2014a](#)). For example, providing multilingual exhibit texts and program delivery, training staff to work with a diverse range of visitors, incorporating alternative interpretations and different perspectives, and designing opportunities for cross-cultural meaning making within informal STEM learning institutions may be effective ways to create more inclusive experiences for more visitors and participants ([Dawson, 2014b; Rahm and Ash, 2008](#)). Another potential model for reaching a broader audience is illustrated by the Knowledge rooms project in Vienna, Austria in which science center activities were temporarily offered in empty shops in under-resourced urban districts whose residents did not have easy access to other designed spaces ([Streicher et al., 2014](#)). These “pop-up science centers” were well accepted and utilized by a socially mixed audience because they were welcoming and comfortable for the visitors, easy to access, and were seen as trustworthy actors inside the communities they served. This project showed that by meeting people where they are, we can potentially increase social inclusion in STEM and empower more communities to develop and generate STEM awareness and knowledge. A similar approach has been taken by Guerrilla Science, an approach to informal STEM learning that aims at reaching audiences who may not ordinarily engage with science ([Rosin et al., 2019](#)). Empirical studies ([O’Connell et al., 2020](#)) have shown that Guerrilla Science removes barriers to participation by embedding science into public places where science might be unexpected (access), and designs activities that speak to the identities of participants who might not ordinarily engage with science voluntarily (inclusion).

Addressing adult life-long informal STEM learning

As discussed earlier, research about the effectiveness of informal STEM experiences such as afterschool programs, summer camps, and field trips on youth outcomes is much more prevalent than research about how adults engage in informal STEM activities to support their STEM learning goals. However, several recent studies suggest that informal STEM learning experiences do contribute to adults' knowledge of STEM in meaningful ways. For example, a telephone survey of a thousand adult residents in greater Los Angeles, California, USA, showed that adult informal STEM learning experiences such as reading books and magazines about science and technology, using the internet, and watching science related documentaries and videos were significant predictors of self-reported knowledge of science and technology (Falk and Needham, 2013). Similarly, an international investigation of over 6000 adults living in 13 countries revealed that individuals who used science centers had significantly higher understanding, interest and curiosity, and identity relative to science and technology than did individuals who did not visit (Falk et al., 2016). And an online study amongst amateur astronomers revealed that basic astronomy knowledge was similar to or even higher than that of university instructors if the amateur astronomers were members of a club and had engaged in at least three years of public outreach (Berendsen and Storksdieck 2007; Storksdieck and Berendsen 2007). While these studies begin to build knowledge about the role of informal STEM in adult learning, given the widespread interest in better supporting public understanding of STEM in order to promote more scientifically literate societies, more research is needed to better understand the role of informal STEM resources and experiences in contributing to the STEM learning of adults (American Association for the Advancement of Science, 1994; Brown et al., 2005; Stockmayer et al., 2010).

Documenting long-term informal STEM learning pathways

Despite the long-term, cumulative nature of informal STEM learning, most research to date has been limited in both duration and scope (Anderson et al., 2007). In order to advance the informal STEM learning field, longitudinal studies and innovations in assessment will be essential to better document the construction of STEM learning pathways in order to illuminate how STEM interests and understandings originate and evolve over time across a variety of informal STEM learning contexts and settings (NRC, 2015; Staus et al., 2021a). While there are challenges to investigating long-term learning outcomes in any context, it is particularly the case within informal spaces in which learning pathways are unique to each individual, making it difficult to attribute learning to certain events or experiences (Falk et al., 2018). Similarly, because learners choose what, when and how long to participate in informal STEM learning programs and other activities, it is difficult to follow individuals over time, increasing the chance of potential measurement issues due to attrition (Taplan, 2005). Clearly, researchers will need to develop innovative methods to capture the accumulation of knowledge and understandings derived from multiple sources over longer time frames to address these challenges in future longitudinal informal STEM learning studies.

Introduction

Worldwide, science, technology, engineering, and mathematics (STEM) education is experiencing reform and opening to try to keep pace with the rapidly changing world. Drawing from national and international student achievement data, such as Programme for International Student Assessment (PISA), and statistics from STEM occupations and employment, professional societies call for new educational approaches that simulate real-world complex problems, and focus on the hands-on, interdisciplinary and socially relevant aspects of STEM to improve K-12 STEM education and to build future STEM workforce pipelines.

STEM integration represents a way to think about curriculum change. It is a concept of how to restructure what we teach and what students learn (Herschbach, 2011). Integrated STEM learning could lead to important educational outcomes that include: (1) recognizing system dynamics (Repko, 2008); (2) closing gaps between STEM education from high school to college and the workforce (Tripp et al., 2017); (3) developing workforce skills to cope with complexity (USDA, 2015); and, (4) making scientifically and mathematically sound decisions when students solve problems in a complex designed system (Dym et al., 2005).

Although the theoretical basis for integrated STEM teaching is familiar to many STEM educators, the current educational reform movement no doubt creates certain barriers in the K-12 STEM education system (Herschbach, 2011). In the secondary education level, STEM subjects are typically taught separately, and tend to have disciplinary-specific curriculum models (Herschbach, 2011). Science and mathematics are considered as foundational and formal knowledge and are aligned with standardized tests and discipline-based structure and rules, which could be argued that science and mathematics are focused on preparing high school students for college. In contrast, technology, engineering, and agriculture, are recognized as career and technical education (CTE) career clusters and are considered to be practical subjects that apply some science and mathematics concepts. CTE courses (aka, vocational-oriented courses) are aligned with teaching high school students how to apply knowledge in real-world settings and develop 21st century skills, which could be argued that they are focused on preparing high school students for careers and the workforce. Because each STEM subject has its unique characteristics, K-12 science, mathematics, and CTE educators are overwhelmed about the changes and are unclear on how to navigate these challenges (Wang et al., 2020). In order to successfully integrate STEM subjects in K-12 classrooms, understanding educator's beliefs is the first step and at the heart of effective educational practices of STEM integration (Wang et al., 2020).

By synthesizing current related literature, we start this article by defining STEM integration and describing teachers' beliefs and practices. We provide a new definition of STEM integration that has a broader and development approach to integrated STEM learning after comparing STEM subjects in K-12 education. Next, we share examples of different levels of integrated STEM learning and how teachers' beliefs and practices STEM integration support the role of disciplinary ways of thinking and a broader and developmental approach to integrated STEM learning. At the end of the article, we shared a couple conclusions and identified some challenges teachers will likely navigate when using a broader and developmental approach to integrated STEM teaching and learning.

Definition of STEM integration

Integrated STEM has been ill-defined, and it has become a slogan that yields a myriad of operational definitions and implementation models (Bybee, 2013; English, 2016; NRC, 2014; Scherer et al., 2019). Developing a precise definition of integrated STEM education has been a challenge. Smith and Karr-Kidwell (2000) pointed out integrated STEM is “a holistic approach that links the disciplines, so the learning becomes connected, focused, meaningful, and relevant to learners” (p. 22). STEM integration could signify teaching science and mathematics by integrating engineering and technology into the K-12 curricula (Bryan et al., 2016; Bybee, 2010; Ramaley, 2007), and use real-world problems that relate to learners' everyday lives (Bybee, 2010; Moore et al., 2014; NRC, 2014).

In framing STEM integration, Herschbach (2011) argued there are two basic ways STEM curricula are organized: (1) correlated curriculum; and, (2) broad fields curriculum. Table 1 illustrates our understanding of Herschbach's description of these two curriculum models. The *correlated curriculum* represents a multidisciplinary integration approach where existing content areas retain their formal knowledge structure and teachers coordinate to illustrate interrelationships between or among related content areas. The level of adaptation is limited, and the existing structure of formal knowledge frames the curriculum design and instructional process. The *broad fields curriculum* is an interdisciplinary integration approach where related content areas are reorganized around an activity or sequence of activities. As such, individual subject matters lose their individual identities and the level of adaptation is much higher in coordinating instruction using a new framework that is activity or project-driven.

Moreover, Herschbach (2011) argued that integrating science and mathematics with vocational-oriented subjects (aka, CTE), such as technology, engineering, and agriculture, would help students have an enhanced understanding of knowledge, make learning more relevant, and be more college and career and workforce ready. For example, some scholars agreed that engineering design problems have the potential to help students practice problem solving by using science and/or mathematics knowledge through a systematic and iterative approach (Bryan et al., 2016; NRC, 2014). Table 2 summarizes our analysis of Herschbach's (2011) comparison of science and math to vocational-oriented subjects, such as technology, engineering and agriculture.

Table 1 Comparison of two basic STEM curricula.

Considerations	Correlated	Broad fields
Disciplinary Content areas	Multidisciplinary	Interdisciplinary
Organization of courses	Retains identity of each subject	Individual subjects may lose their separate identities
	Taught as separate subject matter courses	Cluster of related subjects are organized into a single area of study or sequence of related courses
Coordination and planning	Among different stand-alone content areas	Commonly done through a sequence of activities rather than structure of content
Challenges	High level of communication among teachers to reorganize existing subject matter to coordinate relationships among subjects	Clear organizing framework is needed to integrate related content areas into a single course, and structure inherent in existing content areas is lost
Level of adaptation	Very limited	Moderate or substantial
Instructional focus	Formal knowledge taught deductively	Applied knowledge taught inductively through activities (e.g., design process)
Organization of knowledge	Linear and sequential acquisition of knowledge	Non-linear and driven by solving problems

Table 2 Comparison of science and math to career and technical education subjects.

Considerations	Science & mathematics	Technology, engineering, & agriculture
Structure of knowledge	More formal structure “Formal knowledge”	Less formal structure “Applied knowledge”
Kind of knowledge	Conceptual & theoretical	Technical & contextual
Uses of knowledge	Formal knowledge & formal knowledge applied to specific activities	Formal knowledge applied to specific activities & knowledge specific to tasks
Knowledge selection	Non-selective; instruction organized around content	Selective; instruction organized around process and content is selected and applied around application
Purpose of knowledge	Understanding of intellectual content	Utilitarian; skill-training use
Problem-solving	Deductive, theoretical	Inductive, applied
Disciplinary	Single academic subjects of formal disciplinary knowledge	Interdisciplinary and integrated subjects that apply formal knowledge
Epistemological characteristics	S: Discovery and advance knowledge M: Analytical tool and analyses	T: Production and use of abstract and concrete artifacts E: Design of artifacts by selectively using knowledge from STM
Instruction	Independence (stand-alone)	Integrative

A common definition of integrated STEM teaching approaches that is accepted by many scholars is to mirror solving a real-world problem in a complex designed system, where students use knowledge and skills from multiple disciplines that relate to their everyday lives (Bryan et al., 2016; Bybee, 2010, 2013; English, 2016; NRC, 2014; Scherer et al., 2019). We argue that there needs to be a more disciplinary inclusive definition of integrated STEM with CTE career clusters to help bridge cross-disciplinary learning to increase the potential of reaching transdisciplinary learning. *Integrated STEM education is intentionally and purposively blending multiple disciplines (i.e., academic and vocational) to help students meaningfully learn and apply academic content through real-world problems framed in designed complex systems and grounded in career and technical contexts that facilitate multidisciplinary, interdisciplinary, or transdisciplinary learning for the development of life-long and workforce development connections and skills.*

Teachers' beliefs and practices

Educators' beliefs shape who they are as individuals and are influential in their decision-making, thinking, and classroom practices (Buehl and Beck, 2014; English, 2016; Margot and Kettler, 2019; Wang et al., 2020). Teachers' beliefs are a fundamental type of the through process or cognition, such as judgment of the truth or falsity of a proposition or assumption (Nespor, 1987; Pajares, 1992), that occur inside teachers' heads and are unobservable (Fang, 1996). Although teachers' beliefs, compared with their knowledge, are stronger predictors of their actions (Fang, 1996; Pajares, 1992), researchers discovered teachers' beliefs and their classroom practices are not always correlated. For example, teachers might hold beliefs in learner-centered teaching, but their instructions may be didactic in nature (Lim and Chai, 2008; Liu, 2011). Many factors, internal and external (Buehl and Beck, 2014), have impact on teachers' beliefs and influence their practices. These factors include administrators and colleagues' attitudes (Fang, 1996), content knowledge and abilities (Buehl and Alexander, 2006; Buehl and Beck, 2014), teacher preparation programs (Rice and Kitchel, 2017), personal interests and disciplinary identities (Ryu et al., 2019), how they were taught as a student (Balschweid et al., 2014), time and resources (Knobloch et al., 2007; Raymond, 1997), curriculum and standards (Buehl and Beck, 2014), years of teaching experiences (Lumpe et al., 2000), school and classroom environments, and school and education-related policies (Lumpe et al., 2000; Pajares, 1992). It is critical to understand the possible internal and external factors that may support or hinder the connections between beliefs and practices (Buehl and Beck, 2014).

Teachers' beliefs in STEM integration

When integrating STEM, often teachers tend to start with the to-be-learned STEM content knowledge, then, using engineering design challenges to engage students' STEM content learning by helping students see the connections between what they have learned with real-world applications (Crotty et al., 2017; Guzey et al., 2017; Wang et al., 2020). Teachers believed that engineering design activities with the hands-on aspect of design challenges increases students' engagement and motivation to learn STEM contents and practicing their problem-solving abilities (Kendall and Wendell, 2012; Park et al., 2017; Van Haneghan et al., 2015). Teachers also believed mastering STEM content knowledge that is relevant to the design challenges is essential before students can solve the problems. Although teachers believed that science, mathematics, and engineering are commonly used together in solving real-world problems (Wang et al., 2011), and they value integrated STEM teaching strategies, teachers feel low self-efficacy and discomfort to employ integrated STEM instruction, if they do not feel they have enough STEM content knowledge (Nadelson et al., 2013). Margot and Kettler (2019) analyzed 25 articles to picture a holistic view of teachers' perceptions of STEM integration. They found five pedagogical challenges: (1) curriculum challenges, (2) structural challenges, (3) concerns about students, (4) concerns about assessment, and (5) lack of teacher support might hinder teachers' willingness to adapt integrated STEM teaching in their classrooms. Ryu et al. (2019) found preservice teachers' competence to implement integrated STEM practices was "limited in terms of content knowledge, practices, nature of reasoning in disciplines other than their own as well as relations among STEM disciplines" (p. 13). Moreover, preservice teachers had limited and simplistic understandings of the disciplines (i.e., mathematics), sub-disciplines (i.e., science) and related disciplinary connections (i.e., agriculture). Limited understanding of disciplinary relations among STEM content areas limited the breadth and depth of STEM integration. Preservice teachers viewed STEM as a checklist approach to integration as they mentioned they needed to include all four content areas. Wang et al. (2020) conducted a case study with six high school STEM and agriculture teachers to explore their beliefs and practices through interdisciplinary collaboration. Their results echoed Buehl and Beck's findings. Several internal (e.g., teachers' personalities and attitudes to incorporate less familiar content) and external (e.g., administration supports) hindrances challenged teachers to implement STEM integration. The internal and external challenges also resulted in two interdisciplinary collaboration models, multi-classroom and extracurricular activity models. In conclusion, teachers' beliefs have impacts on how they perceive and practices STEM integration and interdisciplinary collaboration.

Disciplinary ways of thinking

Disciplines consist of organized knowledge, including core concepts and professional practices, which is supported by foundational beliefs and assumptions that represent a way of thinking in the field. In Table 3, we outlined how different disciplines have different ways of thinking. For example, the nature of science represents how scientists think and solve problems. Engineering and technological design represents how engineers and technologists think and solve problems. Applied and agroecosystem thinking

Table 3 Ways of thinking and problem-solving process of disciplinary.

<i>Disciplinary</i>	<i>Way of thinking</i>	<i>Problem-solving process</i>
Science	Nature of science (scientific method)	Scientific inquiry
Technology & engineering	Design process	Engineering design process
Mathematics	Nature of mathematics (science of order, logic, and representation; mathematizing and structuring)	Reasoning and representation (e.g., patterns, numbers, shapes, and modeling)
Agriculture, food & natural resources	Applied thinking & agroecosystem thinking	Pragmatic experiences (e.g., learning by doing, observations, and conversations) and systems thinking

represents how agriculturalists think and solve problems. Next, we explain these disciplinary ways of thinking and how they can play a role in integrated STEM education.

The STEM disciplines have unique epistemological characteristics that should be understood to maintain the integrity of each discipline and know how they each contribute to integrated learning (Herschbach, 2011). Disciplines accumulate and articulate sophisticated knowledge and understandings through scholarly endeavors (Rogers, 1999), and it is important to learn through different disciplines because students can learn “significant ways of knowing that have been built by thinkers over time and that operate in and shape our society today” (p. 35). These unique epistemological characteristics are considered “ways of thinking,” because this situates these epistemological characteristics within each disciplinary field, especially from a professional and expert’s perspective in the discipline and workforce, and it easier to communicate the concept of how scientists or engineers think. We summarized the ways of thinking for four disciplines in Table 3. A fourth discipline was included because agriculture, food, and nature resources (AFNR) brings an additional and unique way of thinking as a CTE subject area. Solving-problems is a unifying process across all disciplines, yet each discipline has unique epistemological characteristics that represent how a professional in each discipline would be informed by a way of thinking to solve a problem. Although each discipline has defined epistemological characteristics and ways of thinking, some similarities exist across the different disciplinary ways of thinking.

Nature of science is the way of thinking for scientists. Science involves asking questions about the world and then developing scientific investigations to answer the questions (Abd-El-Khalick, 2012). The nature of science is guided by empiricism, inference, creativity, theory, tentatively, and deductive/inductive/hypothetico-deductive inquiry (Abd-El-Khalick, 2012). Teachers use inquiry-based learning as a pedagogy to simulate the scientific inquiry process that scientists use to solve problems. It is important to note that the scientific inquiry process can be conducted in multiple ways to ask questions, collect and analyze evidence, and community understandings of the phenomenon, which also is known as scientific method (NRC, 1996).

Design process is the way of thinking for technologists and engineers (Moore et al., 2014). The argument could be made that engineers are more theoretical and design tools, whereas technologists are more applied and make and/or maintain tools. We see technology and engineering as being complementary in using the engineering design process. The engineering design process is an iterative process that involves formulating or identifying the engineering problem (including researching the problem and identifying constraints), planning a design solution (including brainstorming different solutions and evaluating competing solutions), and testing and evaluating a prototype or model (including data collection and analyses for feedback in redesign). This design process is repeated until a desirable design solution is created (Moore et al., 2014).

Nature of mathematics is the way of thinking for mathematics (AAAS, 1990). Mathematics is a science of order, logic, reasoning, and representation. Mathematicians use a process known as structuring to solve problems. Structuring can be accomplished through mathematizing and modeling. Mathematizing to structure real-world and mathematical problems known as creative structuring processes. Structuring can be notation, diagrams, definitions, analyses, or models to a class of problems that lead to solutions (Selden and Selden, 2005). Selden and Selden explained mathematizing is “a process of consideration and reflection that alternates between two forms—horizontal, during which the mathematics at hand becomes more familiar and is broadened, and vertical, during which new mathematics (notation, algorithms, definitions, etc.) is created” (p. 9). Next, modeling is another form of structuring, which may involve adding structure (e.g., variables, diagrams, equations, functions) to a familiar real-world or mathematical problem “with a view to converting the given problem into a more tractable one in a (or another) familiar mathematical domain” (Selden and Selden, 2005, p. 9). Finally, mathematicians use another form of complex thinking and mathematizing called validation or validating proofs. Teachers facilitate mathematizing for students using inquiry-oriented pedagogy to help students explain and justify their thinking (Selden and Selden, 2005). Mathematics can be used to express ideas or solve problems through analogies of things or natural phenomena abstractly, manipulating the abstractions to illustrate new relationships, and communicating the abstraction to communicate meaning about the thing or natural phenomenon (AAAS, 1990).

Applied thinking and agroecosystem thinking is the way of thinking for agriculturalists. Agriculture as a discipline was informed by pragmatic thought (Mars and Ball, 2016; Talbert et al., 2005), and applied learning in agriculture is rooted in experiential learning and authentic learning (Knobloch, 2003). In agriculture, a common thread was based on inductively solving problems in a real-world context based on four tenets: (1) John Dewey’s learning in context; (2) Seamen Knapp’s learning by doing; (3) Rufus Stimson’s learning through projects; and, (4) William Henry Lancelot’s learning by using knowledge through solving problems and explaining knowledge (Knobloch, 2003). Learning in agriculture has used an integrated model of experiential learning (Croom, 2008) that promotes application of academic subjects through an integrated curriculum (Talbert et al., 2005); (2) connects learning

to thinking and applying knowledge to careers and life-long learning (Knobloch, 2003); and, (3) holistic student development of 21st century skills to become contributing citizens in a global society. Ball and Knobloch (2005) shared, "The pedagogical roles of the agriculture teacher are complex and varied" (p. 55), and it is important that agriculture teachers understand the ill-structured nature of how to teach concepts in the agriculture and food system. Further, Mars and Ball (2016) found agriculturalists' ways of thinking were varied and informed by cultural and generational transmission, individual and community engagement to address local food system needs, and production efficiencies and economic sustainability.

As such, Knobloch (2003) stated that agricultural educators and the development of future agriculturalists was situated in the context of the social, economic, political, and agricultural systems. In the 1970s, system thinking became more prevalent among agricultural scientists and became known as agroecology. Agroecosystem thinking makes food systems decisions that are productive and efficient while being economical and cost-effective, environmentally sustainable, and socially responsible and acceptable to consumers (Aguna et al., 2005; Raven, 2020). Systems thinking considers a system as a whole and how elements of the system interact with each other (Bartlett, 2001; Kasser, 2018; Ponto and Linder, 2011). System thinking considers how different elements of the system affect each other and the intended and unintended consequences of making various decisions (Ponto and Linder, 2011). It is complex to understand how to integrate social, economic, and behavioral sciences into science and engineering (NRC, 2012). Agriculture, food and natural resources helps facilitate the integration of social, economic, and behavioral sciences because the production system is situated in the environmental system to serve consumers in exchange for economic and social value (Raven, 2020). Charoenmuang (2020) argued food systems education is an interdisciplinary education the "encourages reflective thinking and judgment by helping students use analysis, synthesis, and evaluation in problem-solving oriented approaches; and representing a complex view of knowledge to build the abilities to recognize, evaluate, choose among, and integrate multiple perspectives (Hilimire, 2016)" (p. 36–37).

These different ways of thinking can contribute and flavor the integrated learning experience for students. Interdisciplinarity and integrated STEM education is blending different disciplines together to create new meanings or new solutions to real-world problems (Raven, 2020). Because disciplines are defined by a corpus of knowledge and epistemic characteristics, ways of thinking provide a representation of different approaches to how professionals in specific disciplines solve problems. For example, a scientist would solve a problem using the nature of science, whereas an agriculturalist would solve a problem by inductively testing possible solutions based on feedback from the system components. The different approaches to solving problems provide teacher educators more common language to seeing how different disciplines see and approach solving problems differently. This helps facilitate solving complex problems by facilitating different disciplines to blend together and facilitate interdisciplinary learning experiences for students. Integrated learning is more about using a way of thinking that is representative of a discipline and how the ways of thinking inform the learning process when mixing content and context from different disciplines. As such, we provide five examples of how different disciplinary perspectives informed the development of integrated STEM education units.

Integrated STEM examples based on teacher's beliefs

The examples that we provided in this section were developed in two STEM teaching methods courses (and teacher professional development workshop modeled after one of the courses) at a large public university in the US. Predominately, the 3-credit graduate courses aimed to equip graduate students and upper level undergraduate students, as preservice educators, with the knowledge and skills to develop integrated STEM lessons (Wang and Knobloch, 2018; Ryu et al., 2019). As an example, we will describe the instructional process for one of the courses. From week one to week four, preservice educators experienced the nature of S, T, E, M as single disciplines. In addition, they explored their views of STEM integration, both individually and as groups by drawing concept maps. During week five and six, integrating AFNR into STEM was introduced to preservice educators. Different examples of STEM integration were shared in the course to generate discussion of the different characteristics of STEM integration through AFNR instruction. After sharing examples, preservice teachers started to develop their big idea of integrated STEM through AFNR. They were instructed that no one existing integrated model or teaching method is the best approach to teach integrated STEM through AFNR, which supported an openness to facilitate creative thinking using experiential learning strategies (Roberts et al., 2016). Preservice teachers had freedom to develop their STEM integrated lesson plans by using what they believed would be the best integrated model and practices for teaching STEM through AFNR. Then, from week 10 to week 13, preservice teachers conducted a microteaching of their integrated STEM through AFNR mini-units that they developed, and then delivered the mini-units through field teaching. At the end, preservice educators reflected on their teaching experiences to modify their mini-units. The final product of each mini-unit contained three to five lessons, and each lesson was about 45–60 min. These mini-units demonstrated the different structure of integrated STEM teaching when teachers hold different beliefs (Table 4). These examples showed that preservice educators tended to start teaching by being content-focused. Then, they transition to becoming learner-focused by shifting to activities (hands-on learning), problem-based learning, and/or inquiry-based learning.

Single CTE discipline

The *Where'd You Get That?! By-products of Animals in Agricultural Settings* mini-unit was developed by a non-formal educator, who was a licensed high school agriculture teacher. The mini-unit had five lessons that focused on introducing animal by-products (e.g., ice cream, bee wax, and wool) to fifth grade students. The overarching learning objective was "student understanding and knowledge through STEM-related activities by raising awareness of where by-products originate" Each lesson in the mini-unit followed the same instructional structure. A lesson started with reviewing what students had learned from the previous lesson. Then, the

Table 4 Integrated STEM examples.

<i>Disciplinary focus</i>	<i>Disciplinary process/thinking</i>	<i>STEM content knowledge</i>	<i>Contextual knowledge</i>
Single CTE discipline	Applied thinking	None/limited	Understand byproduct from animals, such as wool from sheep Design a hydroponics
Single S/M discipline	Science inquiry & scientific method	S: Force & motion M: Algebra and data interpretation	
Multidisciplinary	Applied thinking & science inquiry	S: Priorities M: Algebra	Understand and connect wool priorities and production
Interdisciplinary	Scientific inquiry, scientific method, & engineering design	S: Priorities, density, and buoyancy M: Algebra and data interpretation T/E: Engineering design	Design a sturdy chair that can pass tensile strength test.
Transdisciplinary	Nature of mathematical (modeling) & agroecosystem thinking	S: Food desert M: Function, logic, and modeling T/E: Google maps & food desert index	Design a food desert index that could be used to weight factors that might contribute to food distribution and economics problems in a local community

educators taught background knowledge about the by-products, such as how people sheared sheep to harvest wool, and how wool was spun into yarn. Then, students did hands-on activities, such as “shaving” cream off of a balloon using a craft stick, which the balloon coated with shaving cream represented a sheep’s wool. Then, the educator asked students about the purpose of shearing a sheep, and usage of wool at the end of the class. When asked how integrated STEM plays a role in the lessons, the educator, who developed the lessons answered, “In my opinion, I feel that STEM [integration] obviously ... like a tool that’s utilized to teach the content ...” As for the STEM content, the educator said, “I wanted them [students] to understand that everyday household items that they see actually come from animals. They [students] did not see these [STEM and AFNR] connections.” The educator’s perspective implied he wanted students to understand applied thinking using agriculture and food activities.

Single S/M discipline

The *hydroponics lab* mini-unit was developed for ninth grade integrated chemistry and physics students by a licensed high school science teacher. The mini-unit included five lessons that focused on conducting experiments to test different variables that might affect plant growth in a hydroponics system. For example, determining the power needed to pump water in a certain height was the learning objective of the *Power vs. Height Pumped Lab* lesson in the mini-unit. Each lesson of the *hydroponics lab mini-unit* followed the same instructional structure. In the beginning of the lesson, the educator proposed a problem, such as how high the water can be lifted by the pump? Then, students used steps of the scientific method to conduct scientific experiments. Students predicted an outcome, collected data, graphed the data, and interpreted data. At the end of each lesson, students reported and explained the relationship between the variables by using their data. The purpose of integrated STEM instruction was to teach science content to be used to solve a problem. The educator, who designed the mini-unit, said, “Students need to solve a real problem at the end of an integrated STEM lesson. So, they’re going to use science concepts whatever it is to solve problems.” As for the STEM content in the mini-unit, he indicated that “Students need to understand and tell me how high the pump can pump the water. So, I gave both variables [time/height]. By doing scientific experiments, they learned the concept of force and motion, and could apply that to modify the water pump in a hydroponics system.” The educator’s perspective was that he wanted the students to learn science content through a deductive approach of scientific inquiry. He wanted students to learn content by working through the scientific process.

Multidisciplinary

The *Sheep Byproducts: Properties of Wool* mini-unit was developed by a non-formal educator, who was a licensed high school agriculture teacher. It had three lessons to educate third graders about sheep and their byproducts from start to finish. In the first lesson, students explored how much wool is needed for everyday products. Students calculated how many sheep it takes to create a ball of wool. The lesson focused on adding and subtracting multi-digit whole numbers and recognizing the relationships between addition and multiplication. The second lesson focused on the properties of wool like its ability to retard fire, and why wool is a desirable fiber that used to design clothes for certain purposes. Lesson two guided students to practice scientific method through science inquiry. Lesson three asked students to use a simple loom to weave a small piece of fabric. Lessons attempted to build on one another but did not have strong connections. Each lesson focused on one STEM subject area, such as mathematics was the main concept that students learned and practiced in lesson one, and lesson two focused on conducting scientific experiments through science inquiry. Although the mini-unit attempted to incorporate engineering design in lesson three, students did not need to use the content knowledge that they learned from the previous lessons to wave a fabric by using a craft loom machine. The educator, who developed the mini-unit, acknowledged the mini-unit did not have every piece of STEM integrated at the same time. Purposeful STEM integration was what the educator believed when she developed her lessons. She indicated, “I don’t want the lessons to feel like they were doing math or science just for the sake of doing it, but for them [students] to understand that math and science are real-world experiences in agriculture that people in the past and today use.” When it comes to the role of STEM concepts, the

educator said, "I feel this is where I put the most effort into, making sure what they [students] were learning was transferable skills like the scientific process and mathematical equations." As such, the educator's perspective reflected she wanted students to learn mathematical representation and applied thinking in a complementary and relevant manner.

Interdisciplinary

The *Ultimate Building Material* mini-unit was developed by a non-formal educator, who worked as technical staff in a wood lab. The mini-unit had three lessons that focused using science concepts, such as buoyancy and density to determine properties of different wood species, and design and make quarter scale chairs. The mini-unit was designed for upper elementary and middle school levels. Students conducted several experiments in the first two lessons to calculate volume, and density of different wood species. For example, students made a prediction if a wood material will sink or float in water and used the data that they collected and analyzed to synthesize how density and buoyancy are related. The first two lessons helped students learn the relative strength of different wood species given their densities. Students followed scientific methods to conduct experiments in lesson one and two. In the last lesson, students used engineering design process, and what they learned about the density and strength of two different wood species in the first two lessons to design and make a chair. Students learned that there are often trade-offs between weight and strength when designing a chair. After students designed and built the chair, they break their chairs on a test apparatus. At the end of lesson three, students used mathematics and science knowledge and skills to analyze the test results and presented them in the class. Lessons built on one another and had strong connections. Students needed to apply what they used in the previous lessons to help them design their final products. The educator, who developed the mini-unit, believed that STEM integration is "using knowledge gained in math and science to create unique solutions to solve problems and for innovation." As for the STEM content, he said, "The lowest level [STEM integration] includes some math calculation, science fact, or using technology such as the internet. This helped students create an awareness of connections between a STEM discipline. The highest level of integration is where the STEM knowledge is applied to solve problems. This often includes designing something using math skills, science knowledge, and technology in a giving context." As such, the educator's perspective indicated he wanted students to learn the engineering design process and test wood product variables using scientific inquiry to solve the problem. Engineering design and scientific method were integrally interwoven and were simultaneously used to solve the design challenge.

Transdisciplinary

The lesson *Barriers to Food Access in Your Community* was the first lesson of the *Design a Greenhouse* mini-unit that focuses on building context for food insecurity in urban areas. The lesson was developed by a per-service technology education teacher. The lesson asked high school students to define "food desert" by weighing various factors, synthesizing statistics and information in order to draw conclusions to create a mathematical model (i.e., Food Desert Index) that can be used to explain their view of food desert. The educator first presented an existing definition of a food desert and asked students to identify the areas of the definition that seemed vague or unclear. Then, she proposed the question "what do food deserts look like in my community?" and asked students to investigate the problem. Students used Google Maps to investigate the number of grocery stores (aka, food markets) where they can buy fresh food in a community, and measure distances and time, such as by walking, taking public buses, driving, when people go to grocery stores. Students also use city data from the local government, such as average income, residents below the poverty line, percentage of residences with vehicles, as other critical factors that could contribute to food deserts in the community where students lived. Students weighed these factors by using a scale from 0 to 40 to describe the severity of a food desert in the community. At the end of the lesson, students needed to create a Food Desert Index equation that could be used to determine the food desert scores in their community, and also can be used to standardize food desert problems in other urban areas. The educator, who developed the lesson, believed critical thinking and systems thinking are the core STEM knowledge that she wanted her students to practice in this lesson. She said, "My view of integrated STEM is not about teaching specific content. Instead of building subject-specific content knowledge, I think integrated STEM should focus on helping students use critical thinking to solve problems," and "The problem needs to be meaningful to students. The boundary of each subject [STEM] is blurry, but each subject plays an important role to help students understand the problem and they are able to solve the problem by using [STEM] in a meaningful way." As such, the educator's perspective indicated she wanted students to learn transdisciplinary by solving a complex community-based problem (aka, food desert) using two disciplinary ways of thinking—mathematically modeling and systems thinking that were integrally interwoven and were simultaneously used to solve the complex problem.

Conclusions

Teachers' disciplinary ways of thinking

Teachers' disciplinary ways of thinking play an important role in integrated STEM learning. Teachers are informed by their previous experiences, funds of knowledge, disciplinary identities, interests, and professional training (Ryu et al., 2019). These sources shape teachers' beliefs and thinking (Pajares, 1992). Because beliefs play a critical role in teacher education to support both preservice and practicing teachers' professional development, such as forming personalized teaching philosophy, motivating student learning, and developing effective pedagogical approaches (Pajares, 1992; Turner et al., 2009), it is important to consider how teachers' beliefs and disciplinary ways of thinking will shape how they design and implement integrated STEM learning experiences. Teacher educators should recognize the role beliefs play in the acquisition of knowledge as well as encourage the reflection that brings beliefs to

the level of conscious awareness to help improve teachers' classroom practices (Caudle and Moran, 2012; Lumpe et al., 2000). As such, teachers' ways of thinking can help frame and focus integrated STEM curricula. For example, if the teacher uses their primary way of thinking to structure and facilitate a lesson, the learning experience will be more strongly anchored in a discipline and make connections with other disciplines. This experience is more likely to be a single discipline or multidisciplinary learning experience. In contrast, if a teacher uses multiple ways of thinking and purposefully structures and facilitates a lesson that engages students to use two or more ways of thinking in complementary or blended ways, then the lesson is likely to be an interdisciplinary or transdisciplinary lesson. The students' ways of thinking that are engaged and expressed in a learning experience is a criterion to determine the level of integrated learning.

A broader and developmental approach to STEM integration

Although content plays an important role in integrated STEM learning experiences, a more inclusive curricular and cross-disciplinary approach of academic and CTE subjects is needed to reach interdisciplinary and transdisciplinary levels of learning. It is important to consider several factors, not just the role of STEM content, to design and facilitate integrated STEM lessons, including: (1) the role of integration in learning objectives (2) the role (i.e., presence and usage); of STEM concepts, content knowledge, and skills; (3) role of learning outcomes; (4) role of the instructor and type of instruction; (5) role of CTE content knowledge (e.g., AFNR); and, (6) role of students' thinking (Wang and Knobloch, 2018). We emphasize the role of students' thinking should play an important part of planning and facilitating integrated STEM learning experiences. Teachers should design integrated STEM lessons to engage students to think in disciplinary ways, whether it be predominately from a single discipline way of thinking or from a blending of two complementary disciplinary ways of thinking. Helping students see how disciplinary thinking helps them solve problems would encourage them to be more creative, critical, and multi-dimensional in finding solutions. Moreover, intersectionality of disciplinary ways of knowing will help students understand the nature of reasoning in disciplines other than their own as well as relations among STEM and CTE disciplines (Ryu et al., 2019), which would help developing multidisciplinary, interdisciplinary and transdisciplinary understandings.

Cross-disciplinary learning experiences should not be superficially regarded as content from different disciplines (Ryu et al., 2019), but as informed by different disciplinary thinking and epistemic characteristics that are exemplified by experts and professionals who were trained in the respective disciplines. A single disciplinary or multidisciplinary approach is a good starting point for teachers who wish to begin and develop their skills to design and facilitate integrated STEM learning experiences. By doing so, students can explore how specific disciplines have a unique way of thinking and how they connect to other disciplines. We embrace that all disciplines can be a starting point for creating integrated STEM learning experiences, and it is not necessary for integrated STEM education to be inclusive of all S, T/E and M content areas. Developmentally, it may be better to transition multidisciplinary learning to interdisciplinary or transdisciplinary learning by focusing on two disciplines that have complementary ways of thinking or the ways of thinking can be blended to solve a complex real-world problem. Contextualizing integrated STEM learning using real-world problems would help students understand how to solve problems using different disciplinary perspectives. We believe that an academic subject and a CTE subject can be used in complementary and blended ways thinking to help facilitate interdisciplinary or transdisciplinary learning experiences for students to experience the academic richness and rigor that comes when solving real-world problems that are complex, authentic, and relevant to students (Knobloch, 2003). Interdisciplinary and transdisciplinary learning experiences may be desirable among teachers who are interested in designing and facilitating integrated STEM learning experiences. However, we argue a continuum of different levels of integrated STEM learning can be used to scaffold integrated learning experiences for both teachers and students to develop their understanding and experiences of meaningful and integrated STEM learning.

The role of students' thinking can be reflected as a continuum of three different levels of STEM integration (Wang and Knobloch, 2018). First, *Exploring STEM* (Level 1) is when a teacher exposes students to one disciplinary way of thinking, but may see the possibility of another way of knowing upon completion of solving a complex problem. For example, the single CTE discipline and single S/M discipline examples showed the educators only used either applied thinking in the mini-unit design by showing where animal by-products come from and how they are used by consumers (e.g., *Where'd You Get That?! By-products of Animals in Agricultural Settings* mini-unit). Next, the educator demonstrated the scientific method by having students test the variables of height and time using a water pump for a closed-loop hydroponics system (e.g., *Hydroponics Lab* mini-unit). Second, *Developing STEM* (Level 2) is when a teacher has a predominant way of thinking that drives the instruction or problem-solving process, but engages students to use a secondary disciplinary way of knowing to introduce students to additional tasks that were part of completing the integrated STEM project. For example, the multidisciplinary example demonstrated that students could use mathematics in a pragmatic way, which they calculated how much wool is needed to weave a sweater. However, there was a weak connection between knowing how many wools are needed to wave a sweater and how to conduct a scientific experiment to test the properties of wool in the mini-unit. Finally, *Advancing STEM* (Level 3) is when a teacher intentionally and purposefully teaches students two ways of thinking that complement each other in meaningful ways to holistically solve a complex problem. In doing so, students demonstrate higher-order thinking such as systems thinking, critical thinking, creative thinking, and/or complex problem-solving. For example, in the interdisciplinary example, students needed to understand the science concepts (density and priorities) and used engineering design process to design a sturdy chair. Students also needed to use scientific method to conduct experiments to test tensile strength of their chairs. As for the transdisciplinary example, in order for students to design a mathematical model (i.e., Food Desert Index) to standardize various factors that would contribute to the food desert problem in a community, students needed to rely on systems thinking to evaluate data and make evidence-based decisions to solve the complex problem.

Challenges to implementing a broader approach to integrated STEM learning

Integrated STEM education should be intentional and purposeful in blending multiple disciplines to help students meaningfully learn and apply academic content through real-world problems. These problems should be framed in designed complex systems and grounded in career and technical contexts that facilitate multidisciplinary, interdisciplinary, or transdisciplinary learning for the development of life-long and workforce development connections and skills. By implementing integrated STEM with CTE career clusters, students will be engaged to solve complex real-world problems and help bridge cross-disciplinary learning to increase the potential of reaching transdisciplinary learning.

We acknowledge that teachers and integrated STEM education specialists will face challenges when implementing this more holistic and broader STEM integration approach in the current K-12 education system and teacher educators, curriculum developers, school administrators, and professional development specialists can play important roles in helping teachers to navigate these challenges. First, K-12 teachers are traditionally trained to teach domain-specific content. Domain-specific teacher preparation programs impact teachers' beliefs (e.g., teaching philosophy) and classroom practices (Taconis et al., 2001; Wang et al., 2020). Teachers feel neither they have enough expertise to incorporate subject outsiders of their disciplinary (Baker et al., 2015; Graves et al., 2016), nor do they have abilities to align their domain-specific content with other subjects through the lens of interdisciplinary collaboration (Frykholm and Glasson, 2005). Consequently, how teachers trained in one of the STEM domains are not equipped to incorporate other STEM subjects into their teaching becomes a growing concern to promote integrated STEM instructions. Second, STEM integration needs a high level of on-going planning and coordination among different subjects (Herschbach, 2011; Capraro and Jones, 2013). However, inflexible class schedules, overloaded daily work, and stringent timelines for implementing curricula discourage the interdisciplinary nature of integrated STEM curricula and instructions (Lesseig et al., 2017; Wang et al., 2020). Finally, the STEM integration reform movement is widely recognized in science education (Bybee, 2010, 2013; NRC, 2014), but not in other subject areas. For instance, in the US, secondary science teachers are under stress to adapt their teaching from disciplinary silos to become more integrated styles, but not in other subject areas. Additionally, current secondary education, such as high schools, are structured in ways that continue to encourage teachers to stay in their teaching disciplinary silos (Boyd, 2017). The culture and structure of secondary education might hinder interdisciplinary collaboration to develop and implement integrated STEM curricula and instructions.

Summary

Integrated STEM learning has been growing and developing across many disciplines in the last 20 years. Because of this growth and interest among many disciplines, we believe the future of integrated STEM is exciting as educational professionals align the K-12 curricula and teacher professional development and education programs with complex real-world problems that drive what professionals in different disciplines are working on every day, and that students will work on in their future careers someday. By preparing students to learn how to solve complex problems in new interdisciplinary and transdisciplinary ways, we can hope there are new solutions to improve the way teachers teach, students learn, and professionals collectively solve complex challenges in the 21st century. Bringing academic and vocational disciplines together in education will model how interdisciplinary and integrated teams in the workforce solve complex real-world problems.

Introduction

Science, technology, engineering, and mathematics (STEM) education has increased in popularity ([Moore et al., 2020](#); [Ehlert and Roberts, 2021](#)) around the world. Research and policy positions focused on increasing access to STEM education exist in many countries including the United States (e.g., [Mohr-Schroeder et al., 2014](#); [National Research Council, 2014](#)), the United Kingdom ([Laconte, 2020](#)), Ethiopia (e.g., [Melak and Singh, 2021](#)), South Korea (e.g., [Kang, 2019](#); [Korean Ministry of Education Science and Technology, 2011](#)), Australia (e.g., [Office of the Chief Scientist, 2014](#)), Indonesia (e.g., [Arivina and Jailani, 2020](#)), and Pakistan (e.g., [Ramzan et al., 2021](#)). STEM education has been positioned as a solution for societal and economic needs. For example, some argue STEM education is necessary for people to function in a rapidly changing world increasingly driven by science, technology, engineering, and/or mathematics ([International Technology and Engineering Educators Association \[ITEEA\], 2020](#); [Mohr-Schroeder et al., 2020](#)). Others argue that STEM education should be emphasized to meet national security and workforce needs ([National Science Board, 2015](#); [Maiorca et al., 2021](#)). General fears about falling behind on international test scores also drive an emphasis on STEM education ([Fleischman et al., 2010](#)). These competing rationales for STEM education preview the diverse perceptions found in the current literature.

[Moore et al. \(2020\)](#) synthesized conceptual frameworks and definitions of STEM education. Ultimately, four common themes were identified as most common in STEM education research: STEM education is based on real-world problem solving, individual STEM disciplines share large conceptual ideas and practices, integration strategies vary, and integration relies on structures based in individual disciplines and/or pedagogies ([Moore et al., 2020](#)). Even with these common themes, STEM education research has significant variation in theoretical frameworks and how these practices and policies are enacted. Moreover, the way these STEM practices and policies are enacted often exclude the needs of historically excluded learners ([Berry, 2021](#)). Given this landscape in STEM education, this article has three purposes: (1) synthesize the literature around teacher and student perceptions on STEM education; (2) share perceptions about STEM education research methodologies; and (3) based on the synthesis of these diverse perceptions on STEM education, share implications and recommendations for future research directions.

Teacher and student perceptions of STEM

The emphasis on STEM education directly impacts classrooms as countries, states, districts, schools, and teachers begin to implement STEM learning experiences. The success of these approaches depends upon the success of teachers. Successfully teaching STEM not only requires teacher knowledge ([Nesmith and Cooper, 2020](#)) and affective characteristics, such as dispositions, attitudes, and beliefs ([Thompson, 1992](#); [Philipp, 2007](#)), but also relies on teachers' prior experiences ([Margot and Kettler, 2019](#)). Therefore, it is imperative to understand teachers' perceptions about STEM education.

Teachers' perceptions of STEM

Teachers' perceptions of STEM offer both hope and insight into needed structural changes to effectively implement STEM education in formal settings. Overall, teachers perceive STEM education to be important for their students (Bruce-Davis et al., 2014; Margot and Kettler, 2019; Park et al., 2017; Nesmith and Cooper, 2020). Similar to their students, teachers perceive STEM education to be a great way to apply discipline specific content (Asghar et al., 2012). Teachers also perceive STEM education to be relevant to students' future careers in that real-world problem solving is often interdisciplinary (Bruce-Davis et al., 2014). Within the classroom, teachers believe STEM education can positively impact student learning and learning outcomes (Park et al., 2017) and increase student engagement, interest, and confidence (Dare et al., 2014; Herro and Quigley, 2017; Stubbs and Myers, 2016; Wang et al., 2011). There is also a belief that STEM helps students learn how to deal with failure and how to learn from mistakes (Dare et al., 2014; Roberts and Schnepf, 2020). With such positive perceptions of STEM education, the question must be asked: Why is STEM education valued but not done well in formal school settings? Teachers' perceptions to STEM education suggest the answer lies in structural dysfunctions within the educational system.

One major barrier to effective STEM education in formal school settings is a lack of teacher knowledge (McMullin and Reeve, 2014) from a lack of teacher preparation (Nesmith and Cooper, 2020; Radloff and Guzey, 2016; Stohlmann et al., 2011). Teachers may not know or recognize effective strategies to integrate STEM disciplines (Shernoff et al., 2017) or to implement integrated programs (Nadelson and Seifert, 2013). Other times this focuses on content knowledge and teacher training. For example, typically elementary teachers are not trained for STEM integration in their teacher education programs (Nesmith and Cooper, 2020). Likewise, secondary teachers are often trained in single disciplines (Stohlmann et al., 2011). The lack of effective preparation also leads to teachers being concerned about the role of each discipline in integrated STEM learning experiences (Herro and Quigley, 2017). With this lack of preparation, teachers cannot be expected to effectively implement STEM learning experiences. Moreover, because teachers have less knowledge in STEM, they are less likely to teach it (Nadelson and Seifert, 2013).

In addition to the lack of preparation, teachers also perceive dramatic shifts in classroom functioning to implement STEM learning experiences. For example, teachers regularly highlight the lack of coherent curricula in STEM (Ehlert and Roberts, 2021; Margot and Kettler, 2019; Wang et al., 2011). Without having curricula, teachers need time to collaborate and create intentional STEM learning experiences for their students. Unfortunately, teachers often are not given the time and cite the lack of collaboration and increased amount of time to prepare and implement STEM as barriers to doing more STEM in their classrooms (Margot and Kettler, 2019; Al Salami et al., 2017; Park et al., 2017). Providing STEM experiences necessitates a shift from teacher-led instruction to student-led learning which can be difficult for teachers to implement (Park et al., 2017). Finally, teachers perceive STEM assessments to be lacking in formative assessments (Asghar et al., 2012), in their ability to assess individuals' knowledge of content (Herro and Quigley, 2017), and in alignment to standards and accountability measures such as standardized tests (Nadelson and Seifert, 2013; Ehlert and Roberts, 2021). Although teachers readily identify benefits of STEM, teachers are often evaluated on their instruction and on student learning. If teachers do not perceive appropriate curricular, pedagogical, and assessment tools are available for any subject area, it is logical that teachers would not actively choose to develop and implement these items when they have already identified lack of planning and collaboration time as a barrier to implementation (Margot and Kettler, 2019).

The ways in which schools are structured and teachers are trained creates a system that is not conducive to STEM learning experiences. Student schedules are not designed for cross-curricular or integrated learning time (Margot and Kettler, 2019). Because they are trained in individual disciplines and evaluated on student performance in individual disciplines, different content teachers have different foci when developing STEM learning experiences (Wang et al., 2011). Even then, teachers underestimate students' abilities to solve STEM problems (Asghar et al., 2012) and often think students need specific disciplinary knowledge to participate in integrated STEM learning activities (Wang et al., 2011). Teachers are placed in an impossible position where society emphasizes STEM, teachers see the value of STEM (Margot and Kettler, 2019; Park et al., 2017), but the system is not designed to support teachers or students to do STEM in formal school settings. Expecting teachers to provide high-quality STEM learning experiences without appropriate time and support is irrational. Moreover, as STEM education is still relatively new, people have limited prior experiences with STEM education, particularly in formal school settings.

Research (e.g., Densen et al., 2015; Roberts et al., 2018; Kwon et al., 2021; Maiorca et al., 2021) that noted the structural constraints placed on formal learning environments do not allow sufficient time, integration, and/or access to expertise to develop students' interest in authentic STEM fields. Gupta et al. (2020) studied how the United States public perceived their interactions with STEM. Most participants identified informal learning spaces such as science centers, zoos, and aquariums as places where they encountered STEM, suggesting many STEM education interactions occurring within the informal learning space (Gupta et al., 2020). Informal learning environments promote learning through real-world modeling and authentic examples of STEM work (Nugent et al., 2010; Popovic and Lederman, 2015; Roberts et al., 2018). They occur outside of formal school environments and are often less structured and driven by student interest (NRC, 2009). Given the prevalence of interactions with STEM outside of school settings and the lack of consistent STEM offerings in formal school settings (Roberts et al., 2018), much of the research on students' perceptions of STEM occurs in informal learning environments.

Students' perceptions of STEM

Research on students' perceptions of STEM primarily focus on informal learning opportunities in the form of summer camps or after school programs. This body of research does not consistently define what is meant by perceptions or what is meant by STEM. Often,

constructs like attitudes, beliefs, and motivation are incorporated with the focus on perceptions. Similarly, STEM is not clearly defined with conceptualizations ranging from a math and/or science focused camp to an integrated STEM learning experience. With these limitations acknowledged, four primary themes are evident in research around students' perceptions of STEM learning experiences: (1) STEM learning experiences help students make real-world connections for applications of content; (2) STEM learning experiences often are grounded in the real world with career connections; (3) STEM learning experiences are typically hands-on and practice focused; and (4) STEM learning experiences provide students with access and opportunities to authentic STEM learning.

Students often perceive STEM learning experiences as places where real-world connections and applications of content are provided. An emphasis on real-world learning is central to STEM education broadly (Moore et al., 2020) and students express the benefits of having the real-world connections because it allows them to see how content is applied (Roberts et al., 2018; Densen et al., 2015; Jackson et al., 2021a,b). This is particularly true for students seeing applications of mathematics and science (Densen et al., 2015; Roberts et al., 2018). Robotics is one common way students make connections to mathematics content (Coxon et al., 2018; Wang and Frye, 2019), particularly around ideas of logic, measurement, and decimals (Roberts et al., 2019). Students also made connections to specific topics they learned in school, such as learning about DNA through a DNA extraction activity (Roberts et al., 2018), understanding how the scientific method was applied when designing a prosthetic leg (Bush et al., 2020), and learning about anatomy by dissecting a pig instead of reading about anatomy in a textbook (Jackson et al., 2021a,b). By connecting activities to real-world STEM practices, students see the applicability of the content (Jackson et al., 2021a,b; Christensen et al., 2014; Densen et al., 2015). Importantly, a focus on applied content and curricula is important to the success of historically excluded learners in STEM (Jong et al., 2020). Informal STEM learning environments provide ideal settings for these types of learning experiences for historically excluded learners (Calabrese Barton and Tan, 2018) as formal schooling often reinforces structures (e.g., tracking, siloed-instruction) that negatively impact historically excluded learners (Berry, 2021; Crisp et al., 2009; Martin et al., 2010).

Students can make real-world connections through informal STEM learning experiences that emphasize STEM careers and mentoring. Many informal STEM learning experiences connect the content to the real world by partnering with STEM professionals (e.g., Mohr-Schroeder, 2015). This provides students with authentic learning experiences (Roberts and Chapman, 2017) and increases interest in STEM careers (Maiorca et al., 2021). Informal STEM learning is particularly effective at this because students can see how content is integrated, which they often do not experience in formal schooling where subjects are frequently instructed as siloed-disciplines (Maiorca et al., 2021). Students who participated in informal STEM learning experiences grounded in real-world applications of STEM were 1.8 times more likely to pursue a STEM career than other students (Kitchen et al., 2018). Informal STEM learning opportunities can also increase the chances of students interacting with diverse STEM professionals. This is imperative as non-White and non-male persons are often invisible in STEM professions, which makes it difficult for historically excluded learners to see themselves as members of the STEM community (Jong et al., 2020; Morton and Smith-Mutegi, 2018). Having access to diverse STEM role models helps students see themselves as a member of the STEM community (Coxon et al., 2018) and improve self-perception as a member of STEM (Benavent et al., 2020).

Students also perceive STEM learning experiences to be hands-on and engaged in the "doing" of STEM. Hands-on learning experiences made learning engaging and fun to students (Anand and Dogan, 2021; Bush et al., 2020; Densen et al., 2015; Kwon et al., 2021). Students perceived the informal STEM learning experiences as more engaging because of the constraints they and their teachers have in the formal school setting (Roberts et al., 2018). The way students characterized the engaging, hands-on STEM learning experiences emphasized disciplinary practices (e.g., Standards for Mathematical Practice, Science and Engineering Practices, Technology and Engineering Practices) and doing and making (International Technology and Engineering Educators Association [ITEEA], 2020) as students noted the importance of trying ideas, learning from mistakes, and trying again (Roberts and Schnepf, 2020). Students noted the importance of collaborating (ITEEA, 2020) in completing hands-on projects and 3-D printing (Anand and Dogan, 2021). When doing robotics, students noted the importance of being precise (NGA Center for Best Practices and CCSO, 2010) in their programming and the mathematical implications of their trial and error (NGSS Lead States, 2013). Thus, as students perceived the importance of real-world applications of STEM content knowledge, they also perceived important habits of mind and dispositions characterized by disciplinary practice standards.

Informal STEM learning experiences frequently provide students with access and opportunities that they otherwise would not have had. Students typically perceived informal STEM learning environments to be more interesting than formal school environments (Roberts et al., 2018; Densen et al., 2015). For example, students noted the lack of technology in their schools, lack of access to rigorous core content, and lack of access to integrated STEM courses or electives (Roberts et al., 2018). The implication from this finding is the need for each and every student to have access to quality STEM learning experiences because the way in which students have the opportunity to interact with STEM content impacts their desire to persevere in STEM subjects (Jackson et al., 2021a,b). In the United States, many students decide by the eighth grade that they do not want to pursue more advanced STEM (The President's Council of Advisors on Science and Technology [PCAST], 2010) which implies they perceive STEM as not for them because of how the content has been presented to them (Bell et al., 2018). This has long term implications as access to advanced STEM courses in high school is a primary factor in students' decisions to major in a STEM discipline (Jong et al., 2020). Parents also perceive this structural problem with formal schooling in the United States as it is a reason they enroll their children in informal STEM learning opportunities (Anand and Dogan, 2021).

Students typically have positive perceptions of informal STEM learning experiences and recognize the limitations of formal STEM learning experiences in school settings. Parents recognize it, too (Anand and Dogan, 2021). The general public admit that their interactions with STEM happen primarily in informal learning spaces (Gupta et al., 2020). Even so, there has been significant

work within the United States to increase STEM education in formal school settings. The Early Childhood STEM Working Group (2017) called for earlier STEM experiences for students but acknowledged the lack of attention early STEM education received. Pressures related to standardized testing pose an obstacle to integrated STEM (Shernoff et al., 2017; Sikma and Osborne, 2014). STEM specific schools have failed because of systemic constraints that prevent them from being successful (Weis et al., 2015). In addition to the systemic issues, typically in the form of district mandates and federal and state accountability measures, some teachers may not feel comfortable or prepared to teach STEM in an integrated way (Shernoff et al., 2017). It is important to understand why, given the emphasis on STEM education, structures have not been enacted to achieve this goal.

Synthesis of students' and teachers' perceptions

Students and teachers both have great hope for the promise of STEM education. Students see STEM learning opportunities as engaging ways to explore disciplinary content ideas applied to real-world problems (Roberts et al., 2018, 2019; Densen et al., 2015; Jackson et al., 2021a,b). Teachers also recognize the benefits of STEM for connecting content to the real-world and to increasing student engagement and motivation (Dare et al., 2014; Herro and Quigley, 2017; Wang et al., 2011). Unfortunately, systemic barriers at many levels prevent widespread implementation of high quality STEM education. In South Korea, STEM is less popular than other curriculum acronyms such as STEAM (STEM infused with Art) or STREAM (STEM plus Art, Robotics or Reading) as students express high levels of performance in science and mathematics, but very low interest in these activities (Korea Institute of Curriculum and Evaluation, 2014).

In many Latin American countries, Bascopé et al. (2020) suggest there are positive steps toward incorporation of more integrated learning, however, STEM education as a concept is not explicitly referred to as such at the policy level. Students need access and opportunity to high quality STEM education learning experiences in both informal and formal settings. In formal settings, teachers need to be prepared to teach STEM (Nesmith and Cooper, 2020; Park et al., 2017) and have the curriculum and support (e.g., collaborative planning time, flexible student scheduling, adequate assessments) to teach STEM (Margot and Kettler, 2019). Both bodies of literature suffer from a lack of operationalized constructs. STEM is difficult to implement and measure because it is poorly and inconsistently defined (Moore et al., 2020; Pringle et al., 2020). Therefore, it is important to consider basic methodological perceptions of STEM education.

Methodological perceptions, considerations, and approaches in STEM education

Operationalizing STEM

Currently, there is no agreed upon definition for STEM education (English, 2016; Moore et al., 2020; Pringle et al., 2020). For example, Stohlmann et al. (2012) emphasized integrated STEM uses the engineering design process to create a real-world context for learning content within discipline specific courses. Others have suggested integrated STEM engages students in big ideas and skills for at least two individual STEM disciplines through real-world contexts (Roehrig et al., 2012). Roberts et al. (2022) defined integrated STEM as "using multiple STEM disciplines to collaboratively solve real-world problems with the ultimate goal of increasing STEM literacy" (p. 2). The last definition is one of the few that not only defines what STEM education is but what the goal of STEM education should be. Not only do these competing definitions exist, there are even different names (e.g., integrated STEM, STEM education, integrative STEM) and related fields (e.g., STEAM and STREAM). Part of this could be because of misalignment between STEM initiatives and the siloed nature of educational standards (Bybee, 2018). Therefore, STEM research is inherently complex.

Compounding the problems associated with a lack of clear definitions, STEM education also has competing disciplines and epistemological considerations that are foundational to the methods of research undertaken. Even at the federal level in the United States, different agencies define what is under the umbrella term of STEM, adding further ambiguity (Gonzalez and Kuenzi, 2012). Educational researchers in STEM are influenced by the "traditions, languages, and cultures ... [that] define and limit how they understand and explore this world ... [to] draw upon a variety of theoretical frameworks" (Bussey et al., 2020, p. 52). After a critical review of available discipline based educational research in mathematics, engineering, physics, biology, and chemical education, Bussey et al. (2020) concluded that each discipline and related fields of study within disciplines prioritizes different theoretical frameworks, which could prove to be a rich source of interdisciplinary growth and cohesion, or negatively impact the potential for true integration of STEM concepts. Due to the lack of an operationalized definition and varied disciplinary, interdisciplinary, and transdisciplinary approaches to STEM education research, there are significant gaps in foundational methodological considerations in STEM education research (Li et al., 2020).

There is not one preferred methodological paradigm in STEM education research, rather there are diverse study designs, data collection, and analysis techniques used. Li et al. (2020) in a critical review of the state of STEM education reviewed approximately 800 articles published between 2000 and 2018 in 36 academic journals to understand trends in STEM scholarship. The authors found a dramatic increase in published STEM research beginning in 2015, in research encompassing multiple disciplines concurrently of STEM, with global contributions (e.g., USA, Canada, Australia, UK, Israel, Turkey), and a focus on multi-author publications. When considering methodological approaches, a quantitative focus was the most predominant, however, qualitative, mixed methods, and non-empirical studies were well-represented (Li et al., 2020). The rapid evolution of and interest in STEM education research being published in academic journals over the last two decades suggest that the field will continue to shift to meet changing needs.

Integration of STEM

For many, STEM represents any curriculum, instruction, and/or activities pertaining to any of the four disciplines (English, 2016; Li et al., 2020). Developing a culturally relevant geometry curriculum, primary school children building wind turbines, or research on the perceptions of adolescents' robotics designs could all fall under the umbrella term of STEM education. In addition, Krapp (2002) and Krapp and Prenzel (2011) noted that STEM interest is not always domain specific. Rather, students may have a stronger interest in a particular topic within domains but report less interest in the domain itself (e.g., computer programming but not technology). This practice of mono-discipline instruction in STEM has carried over into the instruments used to assess STEM perceptions, attitudes, interests, and content knowledge from both teachers and students, with existing instruments for measuring STEM perceptions commonly focused on collectively assessing individual attitudes, perceptions, or knowledge individually (Thibaut et al., 2018; Roller et al., 2020).

Yet, there is a growing perception in the research and practitioner field that STEM should be treated as an integrated or interdisciplinary model that unites all four fields into something unique (Honey et al., 2014; Holmlund et al., 2018; Gao et al., 2020). Indeed, education standards like the Next Generation Science Standards (NGSS) in the USA, Australia (Australian Curriculum, Assessment and Reporting Authority [ACARA], 2015), and the United Kingdom (UK Department for Education, 2015) suggest an interdisciplinary instructional approach. However in practice, and as evidenced by research, STEM disciplines frequently remain siloed in their respective content areas present challenges when designing appropriate validated and reliable survey instruments (Staus et al., 2020).

Development of STEM integration

The development of STEM survey instruments is ongoing, as the field of STEM Education as an integrated discipline has risen to prominence in the past decade (Thibaut et al., 2018). As researchers apply a variety of theoretical frameworks to understand the perceptions, attitudes, etc. of students and teachers, using qualitative, quantitative, and mixed paradigms, there is space for contributions to the field. Integrated or interdisciplinary STEM approaches have been under-researched, with gaps in understanding instruction, professional development and training, and student outcomes (Griese et al., 2015; Herro et al., 2017; You et al., 2018). Therefore, it becomes necessary from an assessment perspective to be able to measure interest, attitudes, and knowledge in the four elements comprising STEM, while using precise contexts and content area terms, as well as integrated STEM as its own "meta-discipline" to understand how everything works together (Morrison, 2006).

As there is no consensus with an operationalization of integrated or interdisciplinary STEM education, and a documented pattern of assessments that are mono-discipline specific (Gao et al., 2020), there is a critical need for the creation of valid and reliable assessments that encompass the integration of science, technology, engineering, and mathematics. Some of this work has begun, however, the lack of consensus for an inclusive theoretical framework prevents any one singular instrument from being appropriate. Gao et al. (2020) conducted a literature review of available research of integrated STEM educational programs for Grade 6-university students, finding approximately 49 appropriate studies, 40 of which included science with engineering as the dominant disciplines. The authors concluded that although all of the studies were presented as using an integrated STEM approach, the assessments used to measure students' content knowledge were typically specific to a singular discipline. Moreover, the assessments used were chosen or adapted from existing instruments. Less than 15% of the articles chosen included assessments that incorporated an interdisciplinary approach to content knowledge (Gao et al., 2020).

Implications and future directions

STEM education is positioned as important for workforce, national security, and citizens' needs to function in a world increasingly driven by STEM (ITEEA, 2020; Mohr-Schroeder et al., 2020; Maiorca et al., 2021). In education systems, teachers and students perceive significant benefits of STEM education, particularly for increasing student engagement and understanding when content is applied in real-world contexts. However, like many educational initiatives in the past, the enactment of reforms and policies do not typically meet the needs of historically excluded learners (Berry, 2021). As a field, it is imperative to undertake the conscientious work needed to realize the hope many have for STEM education.

Currently, STEM education is not well defined (Moore et al., 2020; Radloff and Guzey, 2016). Clearly operationalized definitions of STEM education must be paramount for moving the field forward. Without operationalized definitions, rigorous measurement of important constructs and concepts cannot occur. This impedes the progress of truly understanding the impact of high-quality STEM learning experiences on teaching and learning STEM. While discipline-specific approaches to STEM continue, other research (e.g., Roberts et al., 2022) encourages an interdisciplinary or transdisciplinary approach to STEM education in both research and practice. Frameworks for integrated STEM practices (e.g., Lowrie et al., 2018; Roberts et al., 2022) and approaches that are grounded in equitable approaches to STEM teaching and learning do exist (e.g., Jackson et al., 2021a,b). The field of STEM education should use these interdisciplinary perspectives to develop and evaluate systems and practices to support the teaching and learning of STEM so that students' and teachers' hopes for STEM education can be realized.

The acronym STEM (Science, Technology, Engineering and Mathematics) represents an integration of the four fields of studies that can remain independent on their own. Since STEM has been introduced in the 1990s by the National Science Foundation of US, it has gained a lot of attention from the education community and it has been a vibrant field of the research area in the past 10 years. From 2000 to 2018, the number of studies on STEM education grew enormously in 36 selected journals. STEM education research has been increasingly recognized and published across the world (Li et al., 2020).

The interdisciplinary nature of STEM education advocates an integrative instructional approach (Sanders, 2009) that has been examined by many studies (e.g., Berlin and White, 1995; Kennedy and Odell, 2014; Stohlmann et al., 2012). Given the complex, ever-changing nature of real-world problems, STEM teachers need to continuously understand and identify the complexity of problems, learn how to integrate various disciplinary knowledge in their curriculum design, and evaluate their instructions. They need to cater for the cultural needs of the students, create multi-facet learning scenarios, and promote higher order thinking skills such as critical thinking to solve the real-world problems (Stillman and Anderson, 2014). Another challenge faced by STEM educators is a lack of common understandings of the comprehensiveness of STEM education (Bybee, 2010; Keefe, 2009). It has been difficult to define what STEM education is, how school pupils' STEM literacy can be developed and consequently to identify effective ways to enhance teachers' proficiencies in teaching STEM. Pre-service teachers particularly experience difficulties to adopt integrative STEM instruction for their inadequate subject content knowledge in different fields (Blackley and Howell, 2015), limited authentic teaching experience in general (Verloop et al., 2001), and the absence of integrative STEM learning environment in the historical, discipline-specific teacher education they have been engaged in. Without clear STEM-related conceptions, pre-service STEM teachers will misunderstand the whole exertion of interdisciplinary teaching and learning, and possibly ended up with frustrations and withdrawal from STEM-related instruction (Atkinson, 2012; Atkinson and Mayo, 2010; Golding, 2009).

Challenges of pre-service STEM teacher education

The challenges of initial STEM teacher training not only stem from the personal factors of the novice teachers, but also from multiple factors such as a lack of evidence-based professional development models, the under-researched teachers' STEM-related technological pedagogical content knowledge and strong support from various stakeholders.

Models of STEM pre-service programmes

STEM teachers require the ability to provide STEM-related experiences to promote pupils' STEM literacy, for which the latter can be defined as acquiring "the knowledge and understanding of scientific and mathematical concepts and processes required for personal decision making, participation in civic and cultural affairs, and economic productivity" (NRC, 2011, p. 5). The call for integrative STEM instruction is coherent with the notion that an integrated mode of teacher preparation (Bragg, 1998) with clear connections between K-12 and higher education (Kalantzis and Cope, 2014; Ledbetter, 2012).

An important aspect of teacher education is to examine teachers' thought processes in making pedagogical decisions. Richardson (1996) claims that attitudes and beliefs are important factors affecting pre-service teachers to decide what to teach and how to

achieve the learning objectives. Due to limited practical experience, pre-service teachers tend to teach in the same way they learned from previous experience (Deemer, 2004; Koballa et al., 2000; Moore-Russo and Waight, 2019). Since STEM pre-service teachers are subject-based trained and neither have interdisciplinary knowledge nor prior experiences and practice to reproduce their teacher identity, pre-service teacher education program and the concurrent STEM-related teacher practicum experience play a vital role in developing their perception of STEM education (Radloff and Guzey, 2017).

Nevertheless there are conflicts between the ideal and realistic initial STEM teacher education. First, the corresponding pre-service teacher preparation should view STEM teaching as boundary-crossing and integrative in nature (Stillman and Anderson, 2014); while on the other it has been difficult to articulate the notion of interdisciplinarity into epistemological and pedagogical approaches (Jenlink and Jenlink, 2019) for the fluidity of STEM and STEM education over the years. Second, an innovative, adaptive and holistic curriculum is uncommon in K-12 STEM education and hence, it is less likely to have favorable impacts on teacher preparation programs. Although STEM education instructional units with exemplars (e.g., Fulmer et al., 2018) can provide clear standards, guidance and tools for novice teachers to reflect on their own instructional design, a research-based curriculum framework would be desirable for educators to propose their customized rather than standardized STEM education curriculum for everyday classroom teaching as well as pre-service teacher preparation. Third, STEM teachers' identity, role and understanding of STEM education have been continuously studied in the field but few have implications on the STEM teachers' initial education. Only a few reported such programs (Babb et al., 2016; Lee and Nason, 2012) which leaves a gap in STEM teachers' initial preparation. All these point toward a need to have effective models of integrated teacher preparation that are supported by empirical evidence for developing future pre-service teachers' subject content knowledge, pedagogical knowledge and attitudes and beliefs.

Technology in STEM education

"Teachers are the single most important factor in the K-12 education system ... Great STEM teachers have at least two attributes: deep content knowledge in STEM, and strong pedagogical skills for teaching their students STEM" (Holdren et al., 2010, p. 63). STEM pedagogy is a collection of the qualities derived from STEM disciplines, including higher order thinking skills, computational thinking, creative designs, esthetic appreciations, and social interactions. These are necessary to advance a new paradigm of STEM teaching.

Eckman et al. (2016) reported that successful STEM teaching demands pedagogical content knowledge (PCK) in inquiry and activity-based STEM teaching practices for teachers to communicate STEM concepts effectively in a way that students can understand. The UNESCO (2008) ICT-CST framework and standards were also designed to assist countries in preparing innovative and self-directed teachers and pre-service teachers who would be able to integrate technology with their interdisciplinary knowledge dynamically in making pedagogical decisions to teach socio-cultural and political issues (Kurup et al., 2019). Using technology in STEM education seems promising to cope with the ever-changing society and align with 21st-century learning.

As STEM teachers should use technology in their instruction, it would be desirable for them to possess STEM-related technological pedagogical content knowledge (i.e., STEM-TPCK) so that they would be proficient in identifying the needs of integrating different disciplines and learning how to synthesize different perspectives to advocate integrative education. STEM-TPCK is not unique to technology teachers who always have to adopt and teach technology. As Sanders (2009) described these teachers:

Many technology teachers are fond of saying they teach science and math[ematics] in their technology education programs. In truth, it is exceedingly rare for a technology teacher to explicitly identify a specific science or mathematics concept or process as a desired learning outcome and even rare for technology teachers to assess a science or mathematics learning outcomes. (p. 21)

The discrepancy between the claim and practices of teachers might not be only accounted for by their beliefs and attitudes, but also due to a lack of STEM-TPCK. The possible ways to develop teachers' STEM-TPCK deserve further investigation.

Support from stakeholders

In the four dimensions framework model, Bybee (2013) reported that the purposes and policy of STEM education were fundamental to guide the policy-maker and educators to develop useful society-based STEM curriculum and instructional materials to inform STEM literate citizens (Kurup et al., 2019; Zeidler, 2016; Zeidler et al., 2005). Moreover, it is desirable to establish clear guidelines to make a balance between the integrative STEM instruction and teaching individual disciplines in highly structured schooling systems. These can be exemplified by: having guidance in disciplinary-based lesson and curriculum to help teachers to experience teaching environments that resemble K-12 school settings (Corlu et al., 2014; Shernoff et al., 2017), pre-service teacher education framework (e.g., framework for reforming preparation of STEM teachers in the US) (Lee and Nason, 2012), or pioneering STEM Education Course (e.g., the five dimensions of engaging learning that conceptualized the teaching preparation program in Canada) (Babb et al., 2016) to train the STEM teachers. By date, training interdisciplinary STEM teachers is usually not an intentional part of the teacher education program and is regarded as a subsidiary (Radloff and Guzey, 2017; Wilson's report as cited in Rogers et al., 2016). STEM teachers often receive training from part of a major methods program or STEM elective courses. This would consequently hinder the development of both STEM education and STEM career manpower pipeline (e.g., Adams et al., 2014; Babb et al., 2016; Bartels et al., 2019; Radloff and Guzey, 2017).

The way forward

Pre-service teacher education is fundamental to prepare and sustain the workforce in the STEM education community and ensure quality teaching. To address the challenges of initial STEM teacher training, it is essential to identify the attributes of STEM teachers, develop models for teacher training, identify useful strategies to support student teachers in building their knowledge base, skills and attitudes and beliefs. From the sociological perspective, support from different stakeholders is crucial for systemic changes.

Attributes of STEM teachers

Attributes or qualities of STEM teachers should be identified when we develop useful pre-service teacher education programs. In other words, the goals (i.e., attributes of STEM teachers) would determine the training models adopted in different social contexts. There has been research on the STEM literacy K-12 students should acquire, but much less on what is expected of the novice teachers after they have received proper training. In view of the interdisciplinary nature of STEM, the qualities expected on the novices may range from generic to specific and should be comprehensive. In general, teachers should be capable to reflect critically (e.g., [Loughran, 2002](#)) on educational practices. STEM teachers should be particularly reflective so that they can respond promptly to the changes in technology, to the characteristics and learning needs of K-12 students such as their attitudes toward STEM and social demands. STEM teachers who are prepared for self-directed learning may have better skills to analyze their practices continuously and solve problems effectively ([Gencel and Saracaloğlu, 2018](#)). This attribute echoes with the purpose of STEM to strengthen individuals' capabilities in dealing with complex and evolving problems. In addition, creativity and STEM education have a tight connection. Teachers with limited learning experience from a creative and divergent environment would consequently confine their motivation and practices to nurture creativity of their students ([Harris and Bruin, 2018](#)). Before STEM teachers would acquire STEM-TPCK, their digital literacy such as managing technological tools, coding and programming, computational thinking, marshalling evidence and data presentation has to be developed. Afterward they should have the opportunity to apply technology in STEM teaching.

Professional development models for pre-service STEM teachers

There have been a number of teacher preparation programs aiming to develop the competencies of pre-service teachers. Despite the successful and failing attempts, there has been a lack of effective professional development models supported by empirical evidence that focuses on developing pre-service teachers' subject content knowledge, pedagogical knowledge and attitudes and beliefs.

[Rogers et al. \(2016\)](#) proposed their "authentic and sustainable 4-pillar model" based on the Project Engage. The four pillars include: facilitating student teachers to gain insights into STEM career by interacting with STEM specialists in career events, bringing them to experience real-world STEM applications by exploring STEM facilities and workplaces, supporting them to gauge STEM knowledge and skills through mentoring programs, and gaining experience about STEM teaching by supporting K-12 students in STEM competitions. The four pillars were built upon the authenticity model proposed by [Strobel et al. \(2013\)](#) that emphasizes K-12 STEM learning should be context authentic, task authentic, impact authentic and personal/value authentic. The project focused on developing pre-service teachers' understanding of subject matter knowledge and pedagogy to foster collaborative inquiry, problem-solving, design thinking, model building and reasoning. The social interactions between the student teachers and STEM-related stakeholders were essential to support student teachers' in their learning. Being one of the very few STEM initial teacher development models, the researchers regarded their suggestion as a "side product" of the project that required further empirical studies to support its usefulness.

The importance of engaging student teachers actively in STEM and STEM education related activities proposed by [Rogers et al.'s \(2016\)](#) echoes well with the first two principles of another framework for reforming STEM teacher preparation ([Lee and Nason, 2012](#)). There are three principles suggested in the reform framework. The first focuses on developing the novices' disciplinary and trans-disciplinary subject content knowledge and pedagogical knowledge, and the second principle emphasizes the development of "situated theoretical knowledge" that would allow the pre-service teachers to reflect on the theoretical underpinnings of the educational practices such as the classroom learning activities and STEM curriculum ([Custer and Daugherty, 2009](#)). A unique dimension suggested by [Lee and Nason \(2012\)](#) is to support the novices to overcome their negative dispositions ([Sherman and MacDonald, 2007](#)) and fears toward teaching "new" STEM. Appropriate beliefs and dispositions are assumed to be built upon better understandings of STEM knowledge and pragmatic experience; while the affective and emotional aspects of student teachers can be taken care of through continuous intervention and reflective practices.

Strategies of pre-service STEM teacher education

The useful strategies of integrative STEM teacher preparation programs have been reported according to the theoretical underpinnings of individual projects. Nevertheless, these programs "implicitly" followed the models suggested in the previous section.

Situated learning in the course design

Preservice teacher education programs usually emphasize on developing the novices' subject matter knowledge and pedagogical knowledge to integrate the four fields in their teaching. [Rinke et al. \(2016\)](#) implemented a STEM block that focused on the process

of technology and engineering to a group of elementary pre-service teachers. At the end of the course, the student teachers showed a significant increase in the content integration of their lesson planning, made better use of engineering and design concepts, and were more confident to teach STEM. Similarly, [Berlin and White \(2010\)](#) introduced the integrative STEM pedagogies to the master program pre-service teachers, involved them to produce teaching packages and carried out action research. Upon the completion of the program, the beginning teachers valued the integrative approach of STEM. Indeed a holistic approach incorporated with situated learning that engages the novices in planning and implementing lesson plans is common in teacher preparation programs (e.g., [Bartels et al., 2019](#)).

Project-based learning

In theory, project-based learning or problem-based learning in teacher education may simulate the ways K-12 students to solve daily life problems in the context of STEM. Pre-service teachers need to learn connecting subject matter knowledge and educational practices with technology so that technological applications can be used effectively in teaching and learning ([Niess, 2005](#)). In [Awad and Barak's \(2018\)](#) study, student teachers carried out scientific inquiries and solved problems on the topic of sound waves and communication systems by making use of information and communications technology (ICT). The integration of technology and content, adoption of blended learning and the use of ICT were found to be useful for improving student teachers' subject matter knowledge and interests in ICT. Consequently their STEM-TPCK would have been developed through the use of technology. On the other hand, the impacts of project-based learning on increasing their self-efficacy were inconclusive. The student teachers in [Awad and Barak's \(2018\)](#) project reported that working independently in an ICT environment distanced them from STEM. As such, more empirical studies would be useful to provide evidence on whether collaborative learning would be necessary for student teachers to develop their STEM teaching competence in an online mode ([Lee and Nason, 2012](#)).

Place-based education

Place-based education provides an authentic, situated learning experience for pre-service STEM teachers. Teacher educators need to model and provide authentic and meaningful experiences that facilitate community building. This would increase the confidence of pre-service teachers as they can find resources readily available. Enthusiastic community partners are also ready to guide them in bridging the theories and practices and overcoming the challenges of teaching through apprenticeship. There are two aspects of field-based STEM teacher training: preparing pre-service teachers with adequate understandings of different fields in STEM and developing them to become competent in teaching.

Teacher preparation should provide more opportunities for STEM student teachers to work in the related industries, particularly at their early stage of training. The government can collaborate with teacher education institutions (TEIs) and industries to introduce student internships, fellowships or summer jobs in the STEM-related industries ([Atkinson and Majo, 2010](#)). The government can increase the incentives for such collaboration through providing subsidies, tax reduction or free time for the mentors to guide their mentees. This would encourage more students to stay in the STEM-related career pipeline.

Another aspect of field-based training can be exemplified in teaching practicum. In [Adams et al. \(2014\)](#) project, the elementary school teachers stayed in a residential field campus for collaborative scientific inquiry about the local natural environment. They explored the STEM content and carried out research and presentation that would be similar to what their future students would do. [Eckman et al. \(2016\)](#) adopted a cooperative education model that is usually adopted in engineering education. It combined academic study with practical work experience to prepare the STEM pre-service teachers in 12 to 16 months. The pre-service "engineering" teachers were placed in urban middle and high schools and regularly met the university instructors. Results indicated that STEM teachers prepared through this education model would exceed their counterparts learning by traditional mode in a few areas: being more reflective in teaching practices, better mastery of central concepts of STEM fields, delivering appropriate instructions to all students, providing differentiated instructions to meet the diverse needs of students, and overcoming the structural barriers to student learning. In conclusion, field-based experience allows the novice teachers to build meaningful connections between theories learned from the coursework and the classroom practices.

Video-based education

Making use of videos showcasing integrative STEM instruction is another possible strategy to open a "window" for the pre-service teachers to enhance their noticing abilities ([Sherin and van Es, 2005](#)) and establish better connections between theories and practices without entering schools. [Radloff and Guzey \(2017\)](#) carried out a video-based intervention – which is relatively rare in STEM teacher preparation – for a group of elementary pre-service teachers in a semester. The participants were guided to analyze and reflect over videos and create lesson plans. The pre-service teachers demonstrated more alignment with the principles of integrative STEM education. Although videos are not a new pedagogical tool in teacher education, this technology has gained more importance in the period of Covid-19 – a time at which pre-service teachers might not have place-based learning (professional practicum) when many schools were suspended. There are two possible ways of using videos in this situation. Similar to [Radloff and Guzey's \(2017\)](#) study, teacher educators can use pre-recorded STEM lesson videos in their programs to develop pre-service teachers' observation, analytical abilities and reflection as a supplement to the missing face-to-face teaching experience in the practicum. In addition, the pre-service teachers may have online professional practicum during school suspension at which they have to observe and/or co-teach the online lessons with their mentor teachers, or they may conduct independent online lessons. Videos of the online lessons taken during school suspension, together with the live online experience of the same lessons, can serve as a catalyst for the pre-service teachers

to develop understandings of what “authenticity” means in a new era of teaching. Such a hybrid mode of learning closely resembles what has been experienced by their future K-12 students in terms of “authenticity”. Pre-service STEM teachers would also be able to develop their STEM-TPCK with the evidence shown in the videos.

Support from stakeholders

The establishment of professional training models for pre-service teachers and relevant practices is closely related to the policies for STEM education. Bybee (2013) made use of an analogy that “the policies are like blueprints for a house” to describe how they are related to the purposes, instructional practices and material development in STEM education. The policies also inevitably affect the teacher professional development, for instance how the educators would develop the novice teachers in interpreting the national/central curriculum, and hence their own beliefs and practices in STEM learning and teaching. Issues such as the extent to which the four fields of STEM can integrate, how they can integrate while maintaining the uniqueness of individual disciplines are also guided by the policies. Frequent changes in and highly structured school curriculum without research evidence would hamper the development of meaningful teacher education programs to prepare the novice STEM teachers.

To achieve a fruitful STEM-focused teacher training program, it requires innovations, collaborations, and decisions from all levels of individuals and governments (Fensham, 2016). Governments can manage the teacher training programs by providing resources to and endorsing the programs offered by teacher education institutions (TEIs) and issuing teacher certificates (Shernoff et al., 2017). For instance, a unique and innovative double major STEM education teaching certificate program was offered by the University of Arizona in response to the call of government (Mohr-Schroeder et al., 2019). This program was the first one in US resulting in a degree and certification that truly prepares teacher candidates as secondary (grades 8 to 12) STEM specialists. The program encouraged future STEM pre-service teachers to engage in a more interdisciplinary and transdisciplinary study through a STEM perspective.

Another example to illustrate the importance of clear government policy was Virginia Tech’s program, the first of its kind in US that was launched in 2006. It served as an exemplar of a STEM-integration paradigm for preparing 21st century educators, leaders, scholars, and researchers to investigate, teach, and disseminate new integrative approaches to STEM education. The integrative STEM education program provided the theoretical and pedagogical premise for technological/engineering (T/E) design-based teaching and learning practices (Mohr-Schroeder et al., 2019) which required various stakeholders to collaborate.

The experience of pre-service teachers in field-based learning as an important part of teacher training is affected by the ethos of the schools and/or industries at which they would spend a lot of time in being guided to observe, practice and reflect (Hardy et al., 2008). A clinically based preparation program of Kentucky, US (O’Brien et al., 2014) that aligned with the National Council for the Accreditation of Teacher Education (NCATE, 2010) provided such an in-depth learning experience. The program allowed the novice teachers to visit various workspaces and have at least 255 h of placement, giving them hands-on experience with adolescents in classrooms and non-traditional settings to foster their STEM education experience in an integrated manner.

In echoing the blueprint analogy (Bybee, 2013), government policy plays a key role in building the STEM teachers’ capacity in dealing with STEM education promotion. The government can further regulate STEM teacher employment, their relocation, exercise power over classroom practices through quality assurance of schools (Corlu et al., 2014), and propose competency frameworks with sufficient professional development support for STEM teachers at different stages of their career.

Future research initiatives

All policies, curriculum and instructional practices and STEM pre-service program models require the support of empirical studies. Future initiatives on pre-service STEM teacher preparation can focus on investigating teaching STEM from K-12 levels, on the effects of particular learning activities on novice teachers’ subject matter knowledge, technological knowledge, pedagogical knowledge, and dispositions and beliefs. Longitudinal studies to reveal the long-term effects of pre-service training, as well as more systematic, comparative reviews of initial teacher education programs would be useful to develop effective models of teacher professional development.

In-service teacher education

Teachers are consistently improving their classroom practice to improve student learning. As preservice teachers, they build an instructional foundation through coursework and curated experiences with students. As in-service teachers, the learning opportunities become more tailored to ensure their ongoing professional growth. These learning opportunities vary significantly and are referred to as in-service teacher education, staff development, professional development, continuous professional development, or professional learning.

As learning opportunities, in-service teacher education programs are often developed with attention to local or national standards or reform documents. They have the goal of assisting teachers in attaining the vision of these documents. In-service teacher education programs can also be structured to help teachers advance professionally, which includes new certifications to be a master teacher, learning how to mentor, or becoming a teacher leader. The different pathways that in-service teachers embark upon are often a result of their instructional needs or their professional goals.

In-service teacher education programs vary significantly in format and by provider. Short-term workshops can allow teachers to learn new skills, while demonstration lessons can highlight an instructional approach. Year-long programs can provide teachers with opportunities to develop, implement and revise curriculum. Faculty in higher education can offer in-service education programs that share new pedagogical or content knowledge, or new instructional approaches. Additionally, school and district educators can provide programs to support teachers in their instructional compliance. Teachers can also form their own learning communities to enhance their classroom practice. Ultimately, the different providers and formats of in-service programs are dependent upon the information that will be shared with the teacher.

It is through these designed programs that teachers are provided with opportunities to enhance their knowledge, instructional practices, skills, or cognitive schema (e.g., beliefs, mindset, attitudes). As teachers engage in in-service education programs, they acquire new knowledge, skills, practices, or attributes that better support the learning of their students. Even though the programs are designed to support learning in specific areas, teachers learn differently. The prior knowledge and experiences of teachers influences how they understand and use presented material. Ideally, in-service programs are designed to meet the learning variations of teachers, monitor the learning of teachers, and adjust to improve the learning of teachers. The ultimate outcome of in-service education is improved student learning (see Fig. 1).

Fig. 1 Framework for in-service education teacher program.

STEM disciplines within in-service teacher education

The discipline associated with an in-service program influences the composition of the activities and the approach of the instructor. Design decisions can involve how to support the subject matter knowledge development of a teacher. A disciplinary approach can emphasize the logical structures of a discipline (Schwab, 1978, p. 246). This syntactical approach varies between different disciplines. In investigative science, for instance, there would be an emphasis on the methods of verification and justification, the use of inquiry, the scientific practices, or the process skills. A disciplinary approach can also be conceptual (Schwab, 1978, p. 246). This substantive approach emphasizes the conceptual connections between and within disciplines. An example would be when the concept of energy is explored or described within biology and physics in a way that is unique to these disciplines, yet highlights the capacity to do work.

Design decisions can also involve the subject matter knowledge that is needed for teaching. Shulman (1986, 1987) first characterized this knowledge as pedagogical content knowledge (PCK), which is unique to teachers and important in transforming subject matter knowledge into learning experiences for students. This teacher knowledge construct has been modified to account for different disciplines. In the sciences and engineering, PCK is considered to be topic-specific, and can include knowledge of students, curriculum, instructional strategies, or assessments (Neumann et al., 2019). In mathematics, the mathematical knowledge for teaching (MKT) construct focuses on common content knowledge, knowledge at the mathematical horizon, specialized content knowledge, knowledge of content and students, knowledge of content and teaching, and knowledge of the curriculum (Ball et al., 2008). In technology, teacher knowledge frameworks are grounded in technological pedagogical content knowledge (TPCK) (Koehler and Mishra, 2009). Technology is viewed as a nimble construct that is responsive to the subject and classroom.

The disciplines of science, mathematics, engineering, and technology (STEM) add to the complexity of the program design. A review of STEM in-service programs found that teacher knowledge and instructional approaches were supported in different ways (Luft et al., 2020). One type of STEM program involved a focus on one disciplinary area and then included another disciplinary area. An in-service program with a focus on science, but opportunities to learn mathematics to explain the phenomenon would be an example. Another type of STEM in-service education program emphasized the different STEM disciplines through a problem or project-based instructional approach. Finally, a few STEM in-service programs blended the different disciplines. In-service education programs on biotechnology or environmental science are examples. Technology had the greatest variation in use across the different configurations of STEM in-service programming.

Teacher participation in in-service education

Data from the Teaching and Learning International Survey (TALIS), which is sponsored by the Organization for Economic Cooperation and Development (OECD), provides information about teacher in-service education participation. TALIS is an important source of data because it is a comparative international education study that collects data on a nationally representative sample of lower grade secondary teachers. By 2018, over 260,000 teachers from 49 countries responded to the survey.

The 2018 TALIS data revealed that teachers participated differently in-service education activities. Among the entire group of teachers, only 49% participated in any formal or informal program, and among new teachers only 22% had an assigned mentor. Schleicher's (2020) report on TALIS also revealed, by country, the number of in-service education activities teachers participated in ranged from 7 to 2.5 in-service activities over a 12-month period. Singapore was at the high end of activity participation by teachers, while France was at the low end. The activity with the greatest amount of participation by teachers (at approximately 75%) was attending courses or seminars and reading professional literature. The in-service activity with the least amount of participation by teachers involved training on peer/self-observation and coaching, and networking.

Scheicher (2020) also pointed out important areas of benefit and need in terms of in-service education. According to the teachers, the most useful activities were those that connected directly to the content they were teaching and involved collaborative approaches to instruction. Teachers also reported that they wanted more support in working with students with special needs, using information and communication technologies, and teaching diverse groups of students.

STEM in-service teacher education

There has been a growing emphasis across the globe in STEM, which is closely related to building economies that are innovative and have the potential of growth (OECD, 2016). A result of this vision are changes in national standards and curriculum that advocate for more individual and integrated STEM coursework. In the United States, for example, the national science standards point to the importance of mathematics and engineering (National Research Council, 2013). Enacting the vision of national/regional standards or curriculum requires that teachers have opportunities to improve their knowledge and instructional practices through different STEM in-service education programs.

At the school level, these standards and curricula are translated into courses that vary in the integration of different STEM disciplines. Some courses are still primarily one disciplinary area with occasional connections to other disciplinary areas. New courses

are emerging that involve more opportunities for integration, which range from one area leading the integration effort to blended ways of integration. Teachers who are faced with teaching these courses will need STEM in-service education programs that support their knowledge and instruction of these integrated courses.

Another challenge in the educational terrain is a shortage of STEM teachers. Some countries are experiencing a shortage of STEM teachers because fewer students are pursuing the teaching profession, or because STEM teachers are leaving the profession in high numbers. With this shortage, STEM in-service teachers are finding themselves assigned to the instruction of STEM courses in which they do not have an adequate background. This phenomenon is referred to as teaching out-of-field and is noted as a global problem (Hobbs and Törner, 2019). Among STEM teachers, out-of-field teaching can range from a few classes to all of their classes. When teachers are out-of-field, they can be completely out-of-field (e.g., mathematics teacher assigned to teach biology), or they can be assigned to teach a discipline in which they have some background (e.g., mathematics teacher assigned to teach physics).

Teaching out-of-field can happen to secondary teachers and elementary teachers. It is more noticeable among secondary teachers because of their qualifications in a subject specific area. Among elementary teachers, out-of-field teaching occurs when the teacher is reassigned to new grade level. The shift in grade level results in an elementary teacher being unfamiliar with the standards, content or curriculum. When STEM teachers are out-of-field, in-service education becomes a necessary way to improve their content background and instruction.

High quality STEM in-service teacher education

STEM education researchers have studied data from in-service education programs to determine the impact of the program on teachers and ultimately students (e.g., Garet et al., 2001; Heck et al., 2008; Johnson et al., 2017). Many of these studies are the result of an analysis of in-service program data associated with the teachers and students. The results of these studies point to design features that should be considered when developing in-service education programs, which support teacher and student learning. The different features have been described previously in Luft et al. (2020). The following paragraphs are a revised version of Luft et al. (2020).

Knowledge focus

STEM teachers benefit significantly when the in-service program has a subject matter knowledge or PCK focus. STEM teachers can enhance their own subject matter knowledge to support their classroom instruction. By improving their subject matter knowledge, STEM teachers improve their depth of understanding of the content area and increase their flexibility with the content they are teaching. When the knowledge focus pertains to student learning within a subject matter area, STEM teachers are better able to respond and support the developing knowledge of students.

Collaborative opportunities

When teachers work together to learn more about a content-based instructional approach or conceptual area, they have opportunities to challenge and refine their own understandings of these areas. Teachers need to collaborate when they are learning new knowledge and instructional approaches, which will enable them to elicit, challenge, contemplate, and reformulate their own understandings about the focal areas of the in-service program.

Appropriate time and resources

Not all content areas take an equivalent amount of time to learn. Some topics are skill based and easy to learn for a teacher. Learning to use a laboratory device, for instance, in the teacher's content area of expertise will not require extensive time. New content areas or new forms of instruction can require more time to learn. STEM teachers need time to experience these areas as learners, undertake them in their classrooms, and then assess the impact of their new knowledge or instructional approaches with students. Ample time ensures that the teachers and students benefit from the in-service education program. In addition, it is important that STEM teachers have adequate resources to use when they return to their classrooms. These resources can include instructional materials, the support of colleagues, or the knowledge or skills of the teacher. In the absence of adequate resources the impact of the in-service education program on the STEM teacher will be diminished over time.

In-service program and school alignment

The content of the in-service program needs to be coherent with the teachers' workplace. This type of coherence exists between the focus of the in-service education program and the instructional content area of the teacher, the curricular materials that the teachers are using in their classrooms, and the standards of the school, district, or region. When there is coherence, teachers are more likely to use the content presented in the in-service education programming. Without coherence, it can be challenging for teachers to implement the in-service education material in their classrooms.

Ongoing program evaluation

The teachers' learning process should be constantly monitored during an in-service education program. The ongoing evaluation of teacher learning is essential in ensuring the in-service program is meeting the learning needs of the teachers. This evaluation involves a pre-assessment of the teachers in terms of their prior knowledge and specific learning needs in terms of the schools' standards. It also involves monitoring the STEM teachers throughout the program to determine their acquisition of the presented material. This can include an evaluation of the teachers using the in-service program material in their classrooms. As this data is collected and examined, there should be changes in the in-service program. Finally, there should be a summative evaluation to determine the attainment of the in-service education program goals.

In summary, high quality STEM in-service education programs are purposefully crafted to support teacher learning and to align with their working conditions. Throughout the program there is ongoing attention to the learning of the teacher, which may result in adjustments in the in-service program.

Design decisions associated with STEM in-service teacher education

STEM in-service teacher education is a multi-dimensional construct. It begins with the professional needs of the teachers and their goals. These are often determined by the teachers or in consultation with administrators. Identified needs or goals should ensure that teachers continue to grow professionally as classroom educators. Ideally, these needs or goals are shared with in-service education providers before they design the STEM in-service teacher education program.

There are three essential dimensions to consider when contemplating the design of a STEM in-service teacher education program. The first decision pertains to the focus on STEM subject matter; specifically, how will the STEM disciplines be integrated? Different conceptualizations of STEM have been suggested by scholars in the field. Honey et al. (2014) suggested that integration involves concepts and practices. Moore et al. (2020) concluded that STEM integration connects to real world problems, involves connecting disciplines by ideas and skills, and has varying degrees of integration. Dare et al. (2019) reported that STEM teachers conceptualized STEM as separate disciplines, used STEM when solving real-world problems solving, or integrated STEM for problem solving.

In one of the few examinations of STEM in-service programs, Luft et al. (2020) found different representations of disciplinary integration (see Fig. 2). The disciplines could be siloed with each discipline emphasized during the program. This type of program often provided specific content instruction for teachers in different disciplinary areas. When STEM in-service programs had two or more disciplines, the disciplines could be: sequential (i.e., one taught after the other); embedded (i.e., one in service of the other); or connected (i.e., two or more integrated to represent a new discipline). Sequential programs involve teachers learning to use problem based or project-based learning and emphasize the individual STEM disciplines. Embedded programs use one or two of the disciplines (e.g., science or engineering) as a setting for additional disciplinary knowledge. Connected programs involve learning new approaches or knowledge that are a result of the disciplinary integration of specific STEM areas (e.g., biochemistry, biotechnology).

There are also variations in the origin of a STEM in-service education program, which pertains to the people offering the in-service program. Some programs can originate outside of a school setting, but still align with the school curriculum or standards. These programs can be developed by individuals in higher education who are testing or promoting new knowledge or instructional approaches, those in informal learning environments, or industry professionals. National STEM organizations can create programs (e.g., conferences, workshops) that support the learning of teachers. Programs can also originate from school administrators who are interested in improving the instruction of their teachers and the learning of their students. Finally, programs can originate from teachers who want to improve their own educational environment. These types of programs allow teachers to support their own learning by examining, for instance, the learning of their students during different activities. Often, the origin of each of these programs contributes differently to the learning of STEM teachers.

There are also variations in the professional learning objectives of STEM in-service education programs, which relates to what the teacher will learn. Programs are often designed to help teachers improve their content knowledge, PCK, or instruction. These programs can include learning additional subject matter knowledge, new instructional approaches, or about curricular changes. There are also programs that target the different instructional needs of STEM teachers. For instance, there are programs for teachers who are teaching out-of-field, or teachers who are new to the field. There are also programs that encourage the professional advancement of STEM teachers, by allowing teachers to build their abilities to mentor or supervise other STEM teachers, or cultivate their leadership capacity in STEM.

Fig. 2 The representation of STEM in in-service education programs.

Fig. 3 Dimensions of STEM in-service teacher education.

Fig. 3 shows how the STEM in-service education program format and duration is a result of how STEM is integrated; who is supporting/offering the program; what is the learning focus. There are different program formats that range from short-term workshops, to extended course work, to yearlong professional learning communities/study groups (see [Loucks-Horsley et al., 2009](#)). Within these different formats, STEM teachers can grow professionally in different ways. They can improve their disciplinary knowledge and instruction, they can work to align or revise the curriculum within their school, or they can study student work to support their own instruction. They can also grow professionally as a mentor of other STEM teachers or learn how to guide the implementation of STEM curriculum.

Emerging developments in STEM in-service teacher education

STEM in-service teacher education is expanding as more individuals become involved in the development and implementation of these programs. Some of the emerging developments offer teachers new ways to contemplate the enactment of STEM in their classrooms. Other developments pertain to the design of the in-service education program. Some of these emerging areas already involve STEM teachers and some are well-positioned to be adapted to STEM in-service education. Ultimately, these are new and emerging areas that provide new ways to enhance the learning of STEM teachers.

An area that is expanding in STEM in-service teacher education pertains to culturally responsive or equitable instruction. These programs have orientations that expand the participation of students in STEM. The culturally responsive approach recognizes that groups of students have been historically marginalized in schools but offers a vision that encourages the success of all students, while affirming their experiences, identities, and histories ([Brown, 2017](#)). An equitable orientation improves educators' actions in order to improve students access to STEM, which has been hindered because of factors such as, race, class, ability, religion, ethnicity, disability, appearance, gender, language, or immigration status ([Bancroft and Nyirenda, 2020](#)). Infusing STEM in-service education programs with culturally responsive or equitable principles enhances how STEM is presented to teachers and students. For example, programs can highlight how different STEM advancements are a result of different cultures, or programs can emphasize ways to make STEM instruction more gender inclusive. The different ways that programs are configured to be more responsive or equitable are often a result of the theoretical framing associated with the STEM in-service education program.

Within the STEM online in-service education environment there are different ways in which teachers can advance their instruction. Teachers can receive information directly from online programs that are designed to improve their instruction. These formal programs are designed with specific learning objectives. There are also informal online programs that consist of networks, sharing platforms, or other collaborative communities. Within these communities, STEM teachers may share information, create different media (e.g., podcasts, blogs), or co-create material (e.g., wikis, collaborative media) ([Dede and Eisenkraft, 2016](#)). The platforms that support these different programs range from computers, to tablets, to mobile devices. Within these different platforms and program orientations, and an adequate internet connection, the potential for teacher learning is unlimited.

Personalized learning is another emerging area within STEM in-service education. Within a personalized environment, the pace of learning and instruction are optimized through the monitoring of teacher learning and the differentiation of the program material ([Walkington and Bernacki, 2020](#)). In these environments, teachers engage in just the material they need to achieve a specific outcome. In-service education programs are moving toward programming that can be readily adapted to the learning of teachers. The online environment will be important in developing these personalized learning environments. For STEM teachers who are tackling new content and instructional approaches, these types of programs will be essential. In a hybrid or online format, teachers can be easily directed to different activities, which can better support their learning needs. Ultimately, this may result in reduced professional development time, or supplemental learning opportunities for teachers. For in-service teacher education providers, the proliferation of educational material on the internet is a resource that can support personalized programming.

Another area that is emerging in STEM in-service education pertains to the development of the teacher as a person. Bell and Gilbert (1996) initiated this discussion in the science education community when they suggested that teacher development involved social, personal and professional development. The social component involves reframing one's view of being a teacher, which occurs as a teacher interacts with colleagues. The personal component involves navigating the emotions and knowledge that come with being a science teacher. The professional development component involves how teachers draw upon, enact, and support the different activities they use in the classroom. Korthagen (2017) called for more attention to the person in the in-service education experience. This involves planning for the cognitive, emotional, and motivational dimensions of learning during the in-service education program.

Studying STEM in-service teacher education

The global expansion of STEM in-service teacher education is underway. As teachers engage in these programs, there will be opportunities for research that will shed light on the learning of teachers and students. Within the variation of studies that are planned and carried out, some of the most important studies will be conducted to examine the design of different STEM in-service teacher education programs, study STEM teacher and student learning, and consider the role of context during and after STEM in-service education programming. Within these broad areas, there are some priority research areas.

One of the more pressing questions in STEM in-service education pertains to how teachers learn and enact the STEM disciplines. Most in-service education programs are often configured to build a teacher's knowledge and practices in one discipline. The addition of STEM adds a dimension of complexity to an in-service education program but is essential in supporting STEM teachers. One type of question that is important pertains to understanding how an integrated STEM in-service education program improves the disciplinary knowledge of a STEM teacher. It may be that one disciplinary area acts as an anchor for the teacher's learning of other disciplinary areas, or that disciplinary areas are constructed independently of each other. Additional questions that are focused on teachers can involve their emotions or identities when learning about STEM.

Another pressing question pertains to the representation of STEM knowledge in the classroom as a result of the in-service teacher education program. Understanding the supports in a program that can help a teacher enact STEM lessons will be important. For instance, it may be that there are high leverage professional development activities, which can support STEM teachers in enacting STEM lessons. For instance, more change in the instruction of a teacher may result from studying instructional materials than does viewing and analyzing videos of successful instruction, or that building one's interdisciplinary knowledge is essential before a lesson can be enacted with students.

Attending to context is important in the enactment of STEM in-service education programs. School policies, students, or the school community can impact how teachers implement STEM instruction in their classrooms. For instance, it is important to understand how teachers enact novel STEM instructional approaches in their classrooms after an in-service program. It may be that student enthusiasm can support the use of novel instructional approaches. It is widely acknowledged that context is important, but an increased student interest in STEM may be a new dimension of context.

Within these areas of study, there should always be a focus on the teacher, as this is what will help inform STEM in-service teacher education. As these studies are designed, they can be exploratory and make initial statements. This type of study allows for new ideas or approaches to be investigated and conceptualized for potential examination. With some evidence from exploratory studies, impact studies can be conducted that elucidate specific conditions, events, or attributes. Impact studies that accumulate additional evidence can eventually result in effectiveness studies. These studies can compare and contrast specific conditions, events or attributes at a larger scale and demonstrate an impact on teacher learning. These studies do contribute to our expanding knowledge base and are important in future work with teachers in the area of STEM.

In the 2015 Trends in International Mathematics and Science Study (TIMSS), 4th- and 8th-grade students in several Asian countries performed considerably higher on average on assessments of mathematics and science knowledge than their counterparts in the United States and a number of Western European nations (Provasnik et al., 2016). In addition, on the 2018 Program for International Student Assessment (PISA), 15-year-olds from Asian nations scored much higher on average on assessments of mathematics and science knowledge than 15-year-olds in the US and most Western European countries (Organization for Economic Co-operation and Development [OECD], 2019b). While numerous factors likely contribute to these differences in student performance, in this article we examine the nature of mentoring and induction programs for beginning STEM teachers in three Asian countries (i.e., Singapore, Japan, and Shanghai [China]) and compare them to such programs for novice STEM teachers in Australia and France. We also draw on research from the US and New Zealand to investigate ways that mentoring and induction programs can help prepare beginning teachers to work effectively with culturally diverse students. Finally, we review research from the US on characteristics of mentoring and induction programs that are associated with novice STEM teacher effectiveness.

In this article, *STEM teachers* are defined as (a) science, technology, engineering, and/or mathematics teachers who work at the secondary level or (b) teachers who teach mathematics and/or science at the elementary level, including multiple-subject teachers who also teach reading/language arts and/or social studies. We use the term *induction programs* to refer to formal support programs for 1st-year teachers and sometimes 2nd- and 3rd-year teachers that are provided by school districts, schools, or other organizations. Such programs typically feature formal mentoring, orientations prior to the start of the school year, and regular professional development activities. Induction programs sometimes include mentor training, release time for 1st-year teachers and mentors, and formative or summative assessments of beginning teachers. In contrast to *induction programs*, the term *induction* refers to the career stage that usually comes after pre-service teacher education. This period often lasts about two to four years or until the beginning teacher achieves more permanent employment status and/or a regular/professional teaching certificate or license. Individuals who enter teaching through alternative certification pathways and become full-time teachers of record while they are completing education coursework are often in the preparation and induction stages simultaneously (Youngs et al., 2019).

In the first section of this article, we present a conceptual framework that outlines ways in which mentoring and induction programs for beginning STEM teachers across national contexts can promote instructional quality, culturally relevant instruction, and teacher effectiveness. The second section describes mentoring and induction programs in Singapore, Japan, and Shanghai, and compares them to such programs in Australia and France. We argue in this section that mentoring and induction in Asian countries tend to focus on centralized standards for teaching practice; collective responsibility for improvement; professionalizing the career of teaching; connecting theory to practice; and coordinating teacher preparation, induction, and evaluation in relation to national standards. In contrast, such programs in Western nations are typically decentralized and place less emphasis on centralized standards for instruction, professionalizing teaching, or collective efforts to improve instruction.

In the third section, we review research on mentoring and induction programs focused on supporting effective instruction for diverse learning. In this section, we contend that in order to support novice teachers' work with diverse learners, mentors themselves need to have both knowledge about and experience working effectively with diverse students. The fourth section describes characteristics of mentoring and induction programs that promote beginning teacher effectiveness. Here we present evidence from US based research that two years of comprehensive induction has a stronger effect on beginning elementary teacher effectiveness than less intensive approaches to mentoring and induction (Glazerman et al., 2010; Schmidt et al., 2017).

Conceptual framework

Teaching is viewed in different ways throughout the world, and there are multitudinous ways in which teachers enter and are inducted into the profession. Examining different nations' approaches to beginning and continuing teaching yields many insights about the roles that teachers play internationally; such analysis can also turn inward and provide perspective on one's own system of teacher education, induction, and professional development.

It can be useful to use global-comparative exams such as TIMSS and PISA to examine educational practices in countries that perform at the highest levels on these exams. Both of these exams include components specific to mathematics and science achievement. On both tests, in both mathematics and science, for all grades tested, Singapore, Japan, and China are all among the top five countries while Australia and France are mid-level performers (Mullis et al., 2016; OECD, 2019b; Provasnik et al., 2016). There are many factors that affect a country's score on these international exams, including curricula, teacher compensation, and the mindsets of teachers and students. For example, Australian students demonstrate academic resilience across socio-economic brackets, which OECD, the managing body for PISA, attributes to positive school climates and high levels of growth mindset (OECD, 2019a).

While directly connecting specific teacher induction practices to student achievement has posed a major challenge to researchers (for exceptions, see Glazerman et al., 2010; Schmidt et al., 2017), it is valuable to examine themes that emerge related to teacher induction in regions and countries achieving progress and success on international exams. For the purposes of this article, we will examine how teachers in Singapore, Japan, China (Shanghai), Australia, and France are supported as they enter the classroom. Broadly speaking, there is consistency in the three Asian countries when it comes to emphasizing collective responsibility for improvement; professionalizing the career of teaching; connecting theory to practice; and coordinating teacher preparation, induction, and evaluation in relation to national standards. The second and third sections of our article consider several core questions outlined by Britton et al. (2003) as they relate to these themes. First, they ask about the focus of induction systems. Second, they examine the curriculum of induction systems and whose knowledge is being shared with beginning teachers. Third, they ask about the structure of the overall system of induction (Britton et al., 2003). In the fourth section, we address a different question raised by Britton and colleagues: whether or how teacher induction contributes to student achievement.

In a broad study of induction in OECD countries, teacher participation in induction and in-service professional development programs contributed to the mean overall country score for teacher professionalism (Schleicher, 2016). In correlating these scores with PISA results, ultimately, there was a weak association ($r = 0.285$), probably because isolating information about any one component of teacher training, professionalism, and induction on a national level is difficult to do. Even comparing the rates of access to and participation in formal induction programs with a country's PISA scores does not yield a conclusion about the association between teacher induction and student achievement using PISA data. This more recent data suggests that Britton et al.'s conclusions about the connections between teacher induction and student achievement still being tenuous, complicated, and lacking sufficient variability to make distinctions among programs have remained true over the past two decades in most countries (Britton et al., 2003; OECD, 2019a).

Table 1 summarizes the structure of induction programs in each of the countries examined in this article. Structure refers to the overall format and organizing body of induction programs and standards; level of experience targeted refers to when in a teacher's career induction takes place; focus and curriculum refer to the content of induction programs; and purpose refers to the reasoning provided by governments and officials for providing induction programs.

Induction programs in Singapore, Japan, Shanghai, Australia, and France

Singapore

Though a direct link between teacher induction practices and student performance is hard to demonstrate, Singapore has had a great deal of success on international testing for the past two decades, showing consistently high and increasing scores from 1999 to 2015 for both mathematics and science in grades 4 and 8 (Mullis et al., 2016; Schleicher, 2019; Wang et al., 2003). In the system Singapore has developed since its independence in 1965, teachers are generously supported both financially and socially (Darling-Hammond, 2017) and nearly all beginning teachers in Singapore have access to and participate in induction programs when they begin teaching (Schleicher, 2016). Initially, novice teachers spend their first three days on the job at a nationally-organized induction program called the Beginning Teachers' Orientation Program (Schleicher, 2016).

At this training, novice teachers are inducted formally into the professional "teaching fraternity" (Schleicher, 2016, p. 50). Further induction programs continue during the teachers' first two years that feature nationally-trained mentors, in-service training, and a peer-buddy system, which teachers can take advantage of due to a reduced teaching schedule. These courses and peer and mentor reflections focus on equipping beginning teachers with both the content knowledge and practical skills to handle the pressures of classroom management, instruction, and assessment needed to be a successful teacher (Darling-Hammond, 2017). Throughout a teacher's career, Singapore's Ministry of Education constantly monitors their performance in the areas of knowledge, skills, and attitudes; and provides feedback for improvement and opportunities for advancement based on their performance. These reviews hold greater weight as teachers advance in their careers (Schleicher, 2016). In this way, Singapore's teachers are encouraged to be teachers of high caliber at every career stage.

From initial teacher recruitment to curricula designed by teachers and continuous professional development throughout their careers, Singapore's system is focused on the national ethos of establishing and maintaining excellence in their classrooms

(Darling-Hammond, 2017; Schleicher, 2016). It should also be noted that these programs are coordinated and financially supported at the national level (Darling-Hammond, 2017). There is, simultaneously, a great deal of autonomy and professional expectation for teachers, as schools and mentors are left to direct their own teacher induction programs by defining problems and new practices that will best fit their school environment to address the identified problems. This culture of professional excellence is fostered by teachers and further promotes collaboration within the field toward nationally-defined goals (Schleicher, 2016).

Japan

The overall structure for teacher induction in Japan includes Ministry of Education, Culture, Sports, Science, and Technology (MEXT) guidelines for a one-year induction period for beginning teachers, involving 120 h of in-school professional development and 180 h (one day per week) of out-of-school training (OECD, 2019a; Schleicher, 2019). Professional development in the school consists of working with mentor teachers, subject specialists, and the school principal to address issues related to academic instruction, student guidance, health and safety, and homeroom paperwork. Off-site professional development addresses pedagogical theory, visits to social service agencies and other institutions connected to schooling and student well-being, and volunteering (OECD, 2018).

Japanese education boards prioritize professional development for novice teachers to train them within their school contexts and prepare them for persistent challenges that they face in schools (Fujimara and Mistilina, 2020; OECD, 2019a). The strengths-weaknesses-opportunities-threat analysis of the program, conducted by the OECD, revealed that induction programs following the MEXT guidelines face threats of demographic change and the need to balance autonomy and control with regard to teaching and learning. These threats are managed successfully through reforms focused on excellence, strong subject knowledge, and professionalism of teachers.

These structural shifts have happened during a time when Japan has shown major growth in mathematics and science achievement. Japan's 4th and 8th graders demonstrated a steady increase from the mid-550s up to the 600 range on TIMSS science assessments between 1995 and 2015 (Mullis et al., 2016). During the same period, grade 4 mathematics scores increased in the same range, and grade 8 students mathematics scores remained consistently in the 500s, meaning Japan has been, since inception of the TIMSS testing, a top-scoring nation. Further, when teachers were asked about their participation in professional development, they reported above-average rates of participation in learning about mathematics and science content and pedagogy.

Beyond the training that beginning teachers participate in during their first year, Japanese teachers of all experience levels engage in a "collective enquiry process" referred to as lesson study (Schleicher, 2016, p. 65). Lesson study is designed to support a collaborative culture toward self-reflection and improvement (OECD, 2018). In this process, teachers at all levels of teaching experience work together to build their reflective capacity through research, planning, teaching, and observation. Lessons observed by a team of teachers are used to examine ways for the collective group to improve their practice, supporting collaboration among team members. In this way, the team of teachers is setting the agenda for their own learning, and building on one another's ideas, skills, teaching, and research.

Shanghai (China)

In Shanghai, China, novice teachers' access to and participation in induction programs hovers right around 100% (Schleicher, 2016). The regions of Shanghai, Beijing, Jiangsu, and Zhejiang are separated from the rest of China in the research literature because their 15-year-olds have outperformed all of the other 78 countries participating in PISA on their own. While this group of students is not representative of China as a whole, in an analysis of the 2018 administration of PISA, Schleicher (2019) noted that the population of each of these four regions is similar to that of the other countries participating in the exams. For these reasons, researchers have singled out each region in research, and Shanghai demonstrates particularly compelling teacher induction practices.

Overall, the induction programs in Shanghai are centrally coordinated, requiring novice teachers to participate in 240 h of training in their first five years of teaching, and rewarding more senior teachers with leadership positions in their schools when they participate in 540 h of training over five years at any point in their career. These opportunities to learn are coupled with a lower average number of hours teaching (i.e., 10–12 h per week) to allow teachers to participate in these programs effectively (Schleicher, 2016). This time is spent with teaching and research groups, focusing on content areas and student learning; and classroom groups, focused on serving the same group of students across disciplines to ensure an equitable experience for all students (Zhang and Kong, 2012).

These regionally-coordinated training sessions work in partnership with teacher preparation colleges to ensure access to quality professional development. Induction focuses on creating a culture of collaboration and learning in schools, through mentoring and learning communities, to develop a robust faculty to take on distributed school leadership roles (Schleicher, 2016). When more senior teachers excel in professional development, they have incentives to take on leadership positions within the programs, which develops a shared sense of purpose among faculty to continuously improve their teaching practice as a collective. Thus training is coordinated at a national level, with local delivery by experts who are also embedded in the schools, ensuring that professional development is highly relevant to the context of a given school.

Shanghai teacher professional development features an improvement cycle focused on student learning using data and evidence through a whole system approach, where all members of the school community work to develop a culture of improvement, rather than isolated policy changes (Schleicher, 2016). Through this professional development, teachers are equipped with teaching

methodologies from throughout the world, such as classroom observation and evaluation structures similar to those in Japan, and improving learning through the Montessori teaching method or the mindset of mastery teaching from Bloom in the US (Zhang and Kong, 2012). This openness to best practices, coupled with a collective mindset to implement these changes, were a driving factor in improvement of students' PISA scores in 2009 (Zhang and Kong, 2012).

Australia

Australian teachers participate at higher-than-average rates in professional development focused on mathematics and science content and pedagogy (Mullis et al., 2016). Their students have consistently scored in the low 500s on TIMSS in science, and have seen slight increases in their mathematics scores from 1999 to 2015 (Mullis et al., 2016). In contrast to Singapore, Japan, and Shanghai, there is no nationally-organized induction program for beginning teachers Australia. At the same time, all novice teachers are required to complete a probationary period of five years; during this time, they must demonstrate pedagogical content knowledge and promote student achievement in the classroom (OECD, 2019a).

Each school or district authority in Australia can determine how induction will be structured for their new teachers. Across the country, there are a handful of schools and jurisdictions working to connect the content of teacher education programs to the challenges of full-time teaching, and address teacher shortages (OECD, 2019a). Because teacher accreditation standards are determined at local levels, this has left room for teachers and local administrators to establish them. This autonomy to set the direction for the profession of teaching increases teachers' levels of professionalism and self-regulation overall, a theme consistent with other high-performing countries. However, because the standards are not centralized, there is often weak feedback for teacher preparation institutions, and a lack of national focus overall (OECD, 2019a). While there are many opportunities for training and professional development for in-service teachers in Australia, there are elements missing from its approach to induction which could propel the country further.

France

Hovering around the OECD country average on PISA tests, teacher preparation in France has undergone major shifts from a university-centric model to a professional-centric model (Cornu, 2015; OECD, 2019a). Fourth-grade student achievement in both mathematics and science on the 2015 administration of TIMSS also showed that French students are close to the international average (Mullis et al., 2016). As this was the first time French students participated in TIMSS, trend data for mathematics and science is not available; PISA data for reading has been flat since 2000 (Schleicher, 2019).

The French induction system for novice teachers has undergone major reform in the past ten years, moving in a direction contrary to the three Asian countries. Until 2010, beginning teachers in France participated in coursework at teacher preparation institutes, met with mentor teachers, and had a reduced teaching load that enabled them to engage in planning and assessing student work. Between 2005 and 2010, though, French teacher preparation institutes became more professionalized (Cornu, 2015; Howe, 2006). Changes included shifting from a specifically induction-oriented structure in the second year after receiving a Bachelor's degree, to a Master's degree program, where future teachers teach a half-load, write their theses, and prepare for qualifying national teaching exams. This meant that France's model of preparation no longer included induction during a teacher's first year of teaching, but rather shorter-term internships in schools, intended to complement coursework (Cornu, 2015).

As this shift was occurring in initial teacher preparation, responsibility for professional development and induction was shifted from the centralized university system to the more decentralized secondary school system (Cornu, 2015). While goals and standards for teacher education are still set at the national level, the requirement that beginning teachers earn Master's degrees has left induction programs greatly reduced, and they are now integrated into overall in-service professional development for all teachers (Schleicher, 2016). These decentralized and unmonitored activities tend to focus on classroom management, whereas previously, centralized induction activities at universities covered a wide range of topics to support "new teachers in managing a full-time job" (Schleicher, 2016, p. 50).

Research on mentoring and induction programs that promote culturally relevant teaching

There has been relatively little research in the area of induction programs designed to help beginning secondary STEM teachers enact culturally responsive practices and work with diverse student populations. At the same time, there are a few studies of novice elementary teachers, who often teach multiple subjects including mathematics and science, and their experiences with district- or state-sponsored induction programs designed to help them work effectively with diverse students. These studies often include mentors' perspectives with regard to supporting beginning teachers to work effectively with diverse student populations. Most of the studies featured in this section were located in urban school districts in the US while one study took place in New Zealand; none of the induction programs featured in this section are necessarily representative of all induction programs in these countries.

This section focuses on three core questions from Britton et al. (2003): What is the focus of a given induction system? What are the curricula of induction systems and whose knowledge is being learned by novice teachers? And, what is the structure of the overall system of induction in a given jurisdiction? While the studies in this section represent different foci and settings, they converge on two particular themes: (a) in order to effectively mentor beginning teachers to work with diverse students, mentors themselves need to both have the experience and deep knowledge base for working effectively with diverse students; and (b) mentors face multiple obstacles that make it challenging to support novice teachers' development to effectively work with diverse students.

To start, Achinstein and Barrett (2004) conducted a two-year qualitative case study of beginning teacher-mentor pairs in northern California in the US. The study featured 12 schools, 15 novice teachers, and 11 mentors. The schools were described as medium-sized and were located in low-income communities with high percentages of English language learners and low-performing students. The induction program represented a collaboration among a university, county office, and district consortium of educators. The program included two years of on-site weekly meetings with mentors and monthly seminars for beginning teachers. The induction program focused on the California Standards for the Teaching Profession (CSTP) and featured goal setting, sharing resources, mentor and novice conversations about lesson planning, mentor classroom observations, post-observation conferences, modeling lessons, and analysis of student work.

Achinstein and Barrett (2004) focused on what frames (beliefs and attitudes) mentors and beginning teachers had toward diverse students; what pattern frames were used in mentor-novice reflection conversations; how frames were used differently by mentors and novices; and how mentors supported them to reframe their views. In their study, the authors drew on audiotapes and transcripts of mentoring conversations, interviews with beginning teachers and mentors, and videotaped classroom observations. The researchers found that novice teachers were generally situated in the managerial frame (classroom control and student compliance). Mentors had to use reframing conversations to help shift their perceptions of how to work effectively with diverse students—which included political (social change) and human relation (relationships between individuals) frames. The mentors who reframed novices' perceptions of students enabled them to see and learn about their students and were able to focus on areas such as curriculum and instruction—which also bolstered novices' classroom management. However, some mentors attended only to classroom management and this limited beginning teachers' practice to support diverse learners. The researchers made it clear that mentors need to be aware of what types of conversations (or frames) predominate mentor-novice conversations and they need opportunities for professional development to develop skills in reflection conversations to reframe beginning teachers' beliefs and classroom instruction.

While mentor teachers need to be able to reframe conversations for beginning teachers, they must also have deep knowledge about working with diverse students. Achinstein and Athanases (2005) investigated the knowledge base that mentors should have with regard to diversity and equity, and what it looks like in practice. They used questionnaire responses of 37 veteran mentors and new teacher program directors in the Leadership Network for Teacher Induction (LNTI) to define this knowledge base. LNTI is a reform network in northern California of induction leaders who support approximately 2750 new teachers in 60 school districts, many of which served high percentages of English Learners. The focus of LNTI included developing members' knowledge of practice through inquiry projects. These projects mainly focused on critical educational issues through learning and collaboration. In particular, LNTI focused on equity, diversity, and anti-racist practices. In analyzing survey data from the induction leaders, the researchers found that mentors needed both a bi-level knowledge base (knowledge of teaching and knowledge of mentoring) and a bi-focal perspective (focus on local and larger perspectives). Induction leaders believed that mentors needed knowledge of what diverse learners bring into classrooms; knowledge of pedagogy related to diversity and equity; and knowledge of oneself related to diversity and equity (Achinstein and Athanases, 2005).

As part of their study, Achinstein and Athanases (2005) also conducted a qualitative case study of one mentor-novice pair to examine what mentors' knowledge looked like in practice and its complexities. The induction program was designed to provide two years of support for beginning teachers with on-site weekly meetings with mentors and monthly seminars. In the case study, the mentor was able to focus on practices related to diversity and equity but faced multiple challenges. One challenge was finding a balance between sharing with their mentee how to improve their practice without reducing their self-efficacy and willingness to share vulnerabilities. Also, the mentee's principal and colleagues did not engage in practices to promote equity or support diverse learners; and this posed another challenge to the mentor. This finding is consistent with other literature that found that mentors not only need to have both the knowledge and skills to mentor novices for diversity, but they also should be able to challenge the structures, cultures, and conflicting messages present in schools that do not necessarily promote culturally responsive teaching or practices to improve equitable outcomes for diverse learners.

School culture, structures, and messages shared with novice teachers present a unique challenge to mentors especially with regard to culturally responsive teaching and promoting equitable outcomes for diverse learners. Dharan (2015) investigated how schools' cultures, practices, and policies seemed to affect beginning teachers' beliefs, attitudes, and practices in relation to student diversity. The author carried out a qualitative case study of five beginning primary teachers located in urban schools serving students of varying socioeconomic backgrounds in New Zealand. Dharan conducted interviews, classroom observations, and observations of meetings between novice teachers and their mentors. It is unclear how often these teachers worked with their mentors or the structure (i.e., frequency and types) of mentoring that took place. At the same time, Dharan explained that observations of mentor-novice conversations focused mainly on "established ways of working" (2015, p. 69). The mentors rarely focused on diverse students or the *why* and *who* and focused more on the *how* and *what* teaching practices already predominated the school culture.

Novice teachers in Dharan's (2015) study had broad perceptions of diversity that were influenced by their preparation program and they understood the importance of culture and individual diversity; the author notes that this finding is contrary to research that finds that many novice teachers are not exposed to nor prepared for diversity. However, after 12–18 months in the study, while these teachers maintained their definition and understanding of diversity, their instructional practices focused on homogenization through ability grouping based on assessments. In addition, their pedagogy focused on academic ability compared to social categories of teaching and learning. Dharan explained that the focus of these teachers on academic ability and homogenization of classroom practices was shaped by their schools' culture and structures that promoted such practices—and this included mentoring conversations. The author maintained that schools (particularly mentors) and teacher preparation programs need to work in conjunction in order to effectively induct novices to work effectively with diverse students (Dharan, 2015).

A study by Yendol-Hoppey et al. (2009) in the area of mentoring teachers for culturally responsive teaching and effectively working with diverse students echoed the studies mentioned above. In their qualitative study of an urban induction program, the authors focused on mentors' perspectives on how they conceptualized their work to support novice teachers, what challenges they faced working with novices, and how they addressed these challenges. The researchers focused on the Urban Mentoring Program (UMP), which was located in a large school district in the northeastern region of the US. The purpose of the UMP was to provide full-time mentors to schools that were in most need of mentoring services. The UMP selected schools based on the following criteria: 50% or more of the student population received free or reduced-price meals and the school had at least 10 first- and second-year teachers.

During the time of Yendol-Hoppey et al.'s study (2009), the UMP assigned 12 mentors to work in 15 schools and each was assigned to work with 12–15 teachers. The schools included two high schools, three middle schools, and seven elementary schools; most of the novice teachers entered teaching through alternative, non-college of education teacher preparation programs (e.g., Teach for America). Most of the mentors worked in a single school and they spent three-and-a-half days a week in their schools where they coached novice teachers. The researchers explained that UMP was based on the research literature on how to organize and structure induction programs. This included mentors having a daily presence in novices' classrooms, mentors not being part of the novice teacher evaluation process, and mentors utilizing self-selected mentoring practices based on school context and individual teacher needs. UMP mentors engaged with novice teachers in co-planning, preparing materials for instruction, collaborative study of novices' teaching practices, providing and accessing resources, preparing novices for performance evaluations, and coaching for instruction.

Yendol-Hoppey et al. (2009) primarily drew on one-on-one interview and focus group interview data from 12 mentors in the UMP program that they collected over the course of 16 months. The researchers focused on three mentors in their analyses. Echoing Achinstein and Barrett (2004) and Achinstein and Athanases (2005), Yendol-Hoppey et al. maintained that mentors needed to find balance between supporting novice teachers in survival mode (i.e., classroom management, the micropolitics of teaching, and an urban school bureaucracy) and focusing on deeper levels of pedagogical practice. The authors also argued that both mentors and novices need to be committed to social justice in order to effectively focus on both survival and success (i.e., addressing all students' learning and novice teachers' own professional learning). Lastly, the researchers also explained that if retaining teachers and developing their skills is the goal of induction programs, then mentors need to work closely with school leadership. This last assertion relates to Dharan's (2015) contention that school-based mentors need to work closely with teacher preparation programs in order to help foster reframing conversations.

In summary, these studies of mentoring novice teachers for culturally responsive teaching, equity, and social justice converge toward a number of themes. First, in order for mentors to effectively support novice teachers, they themselves need to have a deep understanding of diverse learners and pedagogical skills for teaching them. Second, mentors face multiple obstacles that make the work of preparing novices for diversity particularly challenging. These challenges typically include finding the right balance between supporting novice teachers with technical skills such as classroom management and student control and helping them develop a deeper knowledge of diverse students and pedagogical practices—this relates to what Achinstein and Athanases (2005) refer to as bi-level knowledge (knowledge of teaching and knowledge of learning).

The mentors in these studies also faced the pervasive challenge of dealing with conflicting messages from other school actors (i.e., novices' principals and colleagues). These school actors promoted practices that maintained the status quo—which focused on student control and increasing student test scores. Emphasizing these areas may inhibit beginning teachers from learning about their students' cultures, backgrounds, characteristics, and beliefs along with pedagogical practices that can promote deeper levels of student learning and not just skills to pass a test. In order to mentor novice teachers to effectively work with diverse students, mentors need to work in conjunction with school leadership and teacher preparation programs, and they need to move beyond classroom management and technical skills in order to focus more on curriculum and pedagogical practices (Achinstein and Athanases, 2005; Achinstein and Barrett, 2004; Dharan, 2015; Yendol-Hoppey et al., 2009).

Going forward, a few lines of research should be pursued. First, all of the studies presented here were qualitative and most featured interviews and observations. There is a need for larger-scale, quantitative studies that examine links between mentoring for diversity and outcomes related to diverse students' learning. Second, the studies featured here focused mainly on elementary teachers. There is a need for more research on secondary STEM teachers and how to support them with regard to equity and diversity. Third, while there are mentoring structures identified in these studies (e.g., weekly observations, reflection conversations, monthly seminars), there is a need for more studies on these and other mentoring structures and how they may affect beginning teacher outcomes. The field is starting to develop a strong understanding of what mentors need to know and the challenges they may face, but addressing these gaps will provide researchers and practitioners with a more robust understanding of how induction programs can effectively support novice teachers for diversity and enact skills and dispositions of culturally responsive and socially-just teaching.

Mentoring and induction programs and beginning STEM teacher effectiveness

While the second and third sections of this article described the structure, focus, and curriculum of beginning teacher induction programs in several countries, in this section we turn to a different question: whether or how teacher induction contributes to student achievement. Two recent large-scale, experimental studies in the US have investigated the impact of induction programs on the effectiveness of beginning elementary and middle school mathematics teachers (Glazerman et al., 2010; Schmidt et al., 2017). In one study, Glazerman et al. (2010) conducted a randomized control trial in 17 urban, medium-to-high-poverty school

districts that featured 1009 novice teachers in 418 elementary schools. The teachers taught kindergarten through grade 6; of the 1009 study participants, more than 900 (91%) taught mathematics and were responsible for students' mathematics outcomes. Each of the 418 schools was assigned at random to one of two treatment groups or a control group; one treatment group participated in the Educational Testing Service (ETS) Pathwise induction model and the other took part in the University of California Santa Cruz New Teacher Center (NTC) induction model. Beginning teachers in treatment schools in 10 of the 17 districts received comprehensive induction for one year only while novice teachers in treatment schools in the other 7 districts received comprehensive induction for two years (Glazerman et al., 2010).

As part of the Pathwise and NTC induction models, beginning teachers were assigned to full-time, trained mentors who observed their instruction and used formative teacher assessments to provide them with feedback. In addition, the novices received release time that enabled them to meet with their mentors. Mentors were usually assigned to a caseload of about 12–15 beginning teachers. Novice teachers in the control group received mentoring from a full-time teacher; in addition, beginning teachers and mentors in the control group were much less likely than those in the treatment group to receive release time and mentors were much less likely to participate in mentor training, to conduct classroom observations of their mentees, or to use a formative teacher assessment in their work with them. The teachers participated in the study through the end of their third year of full-time teaching and data was collected on the effects of induction on students' mathematics achievement as well as other outcomes. The authors presented results for the study participants' third year of teaching and reported that impacts on gains in mathematics scores for teachers in the seven two-year districts were positive and statistically significant. At the same time, they found no effect of comprehensive induction on gains in students' mathematics scores for teachers in the 10 one-year districts (Glazerman et al., 2010).

In a second study, Schmidt et al. (2017) carried out a randomized control trial in Broward County Public Schools (BCPS), Florida and Chicago Public Schools (CPS) that included 629 first- and second-year elementary and secondary mathematics teachers and 227 schools. The researchers randomly assigned 342 teachers in 108 schools at the school level to the treatment across the two districts and 287 in 119 schools to the control group. In terms of the treatment, the NTC induction model (described above) was provided to each beginning teacher in the treatment group during their first two years of teaching.

Similar to the Glazerman et al. study, novice teachers in the control group in the Schmidt et al. (2017) study received mentoring from a full-time teacher; novices and mentors in the control group were much less likely than those in the treatment group to receive release time; and mentors were much less likely to participate in mentor training, to conduct classroom observations of their mentees, or to use a formative teacher assessment in their work with them. The researchers examined the impact of two years of NTC induction support on the effectiveness of teachers in grades 4 through 8 in mathematics. They reported that students in grades 4 through 8 of teachers who received two years of induction support performed 0.15 standard deviation ($p < 0.01$) higher on average than students of control teachers; this is similar to moving from the 46th to the 52nd percentile (Schmidt et al., 2017).

Conclusion

During the past 20 years, beginning teacher induction programs for STEM teachers have received significant attention throughout the world. They are typically enacted in order to support novice teachers' development of high-quality instructional practices, help orient them to their schools, provide emotional support to them, and promote their retention. In this article, we drew on scholarship by Britton et al. (2003) to address a series of questions related to induction programs. In particular, in the second and third sections of the article, we examined the structure, focus and curriculum, purpose, and participants in induction programs in several countries and regions. In the fourth section, we turned to the question of the influence of induction programs on student achievement in mathematics.

In the second section, we presented brief descriptions of national approaches to induction in (a) three Asian countries/regions that have consistently performed at high levels on international comparisons of student achievement (i.e., PISA and TIMSS) and (b) two Western countries that regularly perform in the middle range on such assessments. In Singapore, Japan, and Shanghai, induction programs are generally based on national standards for teaching; are often coordinated with pre-service teacher education programs and/or teacher evaluation; link theory and practice; and reflect collective efforts to improve and professionalize teaching. In contrast, Australia and France lack national induction programs; instead, schools and districts in these countries have responsibility for supporting novice teachers and local induction programs are not tied to centralized standards for teaching or collective efforts to professionalize teaching. While many factors contribute to national performance on PISA and TIMSS, it seems that the approaches to induction (and more generally to teacher development) in Singapore, Japan, and Shanghai could be contributing to their students' consistently-high performance on these tests.

In the third section, we reviewed several empirical studies of induction programs that address issues related teaching for equity and diversity and came to two main conclusions. First, mentors are more likely to effectively help beginning teachers learn to enact culturally relevant teaching if the mentors themselves have developed a strong understanding of diverse learners and how to effectively teach them. Such learners can include students who are diverse with respect to race/ethnicity, language, sexual orientation, ability, and other characteristics. Second, in many school contexts, mentors potentially face a number of challenges in their efforts to help novice teachers address issues related to equity and diversity in their instruction; these can include, for example, norms among other teachers, expectations from school leaders, and pressure to follow a prescribed curriculum in mathematics and other subjects.

In the fourth section, we described two randomized control trial studies of the impact on students' mathematics achievement of comprehensive induction programs for beginning elementary and middle school mathematics teachers. In the first study, Glazerman et al. (2010) reported no effect of one year of comprehensive induction on students' mathematics achievement after the first year of teaching or the second year of teaching. On the other hand, the authors found that participating in two years of comprehensive induction was related to gains in students' mathematics achievement after the third year of teaching. In a somewhat similar finding, Schmidt et al. (2017) reported that participating in two years of comprehensive induction was related to gains in students' mathematics achievement after the second year of teaching. It may be that most beginning teachers face so many challenges as they transition to full-time teaching that they are generally less likely to benefit from comprehensive induction (in terms of improved effectiveness as measured by student performance on standardized tests) until their second year of teaching (Youngs et al., 2019). In addition, it may be that as mentors (who are assigned to work with beginning teachers in multiple schools) become more familiar with their mentees' school organizational contexts over time, they are in a better position to support them.

Appendix

Table 1 Overview of induction structures, targets, focus/curriculum, and purpose in six countries/regions.

	<i>Australia</i>	<i>Shanghai (China)</i>	<i>France</i>	<i>Japan</i>	<i>Singapore</i>	<i>California (U.S.)</i>
Structure	Five-year national probationary period; teachers must meet pedagogical content knowledge (PCK) and achievement standards; school or district determined	Regionally centralized; 240 h of training over first five years; additional 540 h of training available later	Recently shifted from nationally centralized to fully decentralized; no structure for induction	A total of 300 h in first year; 120 h based at school, four days per week; 180 h at MEXT training center, one day per week	Three-day national orientation; two years of school-based training with nationally trained mentors	Two years of on-site weekly meetings and monthly seminars; focused on California standards for the teaching profession
Level of experience targeted	First five years	First five years; senior teachers	Shifted from first-year "inductee" teachers to general professional development	First year	First two years	First two years
Focus and curriculum	Locally determined to support national PCK and achievement standards	Regionally-determined standards; data-driven improvement cycle	Shifted from focus on combining theory and practice to preparing for daily responsibilities such as classroom management	Nationally coordinated to support transition into everyday classroom responsibilities; lesson study	Entering national "professional fraternity of teachers;" combining theory with practice	Goal setting; sharing resources; lesson planning; classroom observations; modeling lessons; analysis of student work
Purpose	Teacher retention; professionalization	Building culture of collaboration	Shifted from contextualizing theory to general professionalization	Contextualizing theory in practice as a collective	Establishing and maintaining classroom excellence as a collaborative team	Improve instruction and teacher retention

Introduction

Design-based pedagogy has been developed for fostering the professional practices of middle school math and science teachers. Our work originated out from a professional development summer workshop where we worked in collaboration with teachers to develop math and science lessons that integrated LEGO robotics. Design-based pedagogy was conceptualized out of Ann Brown's (2002) work on design-based research. She highlighted that the role of the teacher is to "entice students" and modify the curriculum in order to change classrooms, as she describes, "from academic work factories to learning environments that encourage reflective practice among students, teachers, and researchers" (Brown, 1992, p. 174). Our research enhances the design-based research literature by adding nuanced epistemological positions. We reposition teachers to be "intellectuals" and "critical leaders" as described by Henry Giroux (1985) and Darling-Hammond (2006), respectively. Drawing on these perspectives, we argue that teachers need to be integral at each stage of their professional work: including curriculum development, instructional design, and professional learning. In doing so, we find that teachers are better positioned to make adjustments in teaching when implementing lessons, modifying future lessons, providing rationales based on their experiences, and ultimately advancing their professional practice as math and science teachers (Devitt et al., 2019a,b).

Epistemological shifts for design-based pedagogy

In Science, Technology, Engineering and Mathematics (STEM) learning, teachers are required to implement curriculum and provide instruction in ways that fosters student learning. However, who makes the curriculum, who selects the instructional practices, and for what purposes (i.e., how learning is assessed) matters in conceptualizing the role of the teacher at each of these pedagogical stages and significantly impacts the quality of STEM learning that occurs. Giroux (1985) takes a strong stand saying, "One of the major threats facing prospective and existing teachers within the public schools is the increasing development of instrumental ideologies that emphasize a technocratic approach to both teacher preparation and classroom pedagogy argues that education is becoming increasingly commodified" (p. 47). In STEM education, this results in textbook companies becoming tasked with determining what math and science knowledge is important and how to impart knowledge on to students. Math and science curriculum become "teacher-proof", recipe-like STEM kits. Norton et al. (2007) describe their concerns with teachers implementing others' curriculum. They found that teachers have difficulty extracting important concepts from activities and fail to utilize the technological materials in ways that promote real conceptual development (Norton et al., 2007). This management style of pedagogy works to consolidate STEM knowledge, reduce complexity for consumption, and enable predefined disciplinary ideas and practices to be efficiently assessed on standardized tests—for the goal of controlling teacher behavior and making outcomes predictable (Giroux, 1985). Universal pre-packaged curriculums do not provide for pedagogical opportunities where localized teachers can flexibly design classroom learning experiences, excite young learners, and prepare them for college, careers, and civic responsibility in STEM areas (NGSS Lead States, 2013).

Instructional practices often endorsed and mandated by school districts contribute to the de-professionalization of teacher practice. In our own research, while engaging in collaborative lesson planning during a professional development on how to integrate LEGO Robotics into math and science lessons, teachers were quick to initiate the lesson planning process using terms like: "Two-fold instruction", "Do now", "recap", "Stop and jot", "Turn and talk", and "cold calling" (Devitt et al., 2018). These practices were popularized and endorsed by Doug Lemov (2015) which he describes as "specific, concrete, actionable techniques" for teaching. These techniques have been institutionalized and standardized across New York City and other large metropolitan areas and often serve as mandated behaviors to be observed on teacher evaluations. These practices are not inherently bad, and could in fact

promote learning in certain contexts. However, as abstracted teaching techniques geared toward supporting memorization, they do not prepare teachers to implement pedagogies that support high-quality learning as described by the Organization for Economic Co-operation and Development. In other words, when placed into a lesson plan with the expectation to be enacted with fidelity, teachers miss the contextual relevance of the learning as it unfolds in the classroom and fail to incorporate or develop the pedagogical practices needed to support STEM learning.

To meet the call set out by [NGSS Lead States \(2013\)](#) in the Next Generation Science Standards (NGSS)—the most current national science standards in the United States, we also frame what students are learning from a global perspective. In 2008, Organization for Economic Co-operation and Development (OECD), responsible for leading Program for International Student Assessment (PISA), described four key points applicable for quality STEM learning: (1) conceptual understanding; (2) connected and coherent knowledge, (3) authentic knowledge within a specific context of use, and (4) collaborative learning. To meet this call in STEM teaching, [Darling-Hammond \(2006\)](#) has argued that the United States educational system needs teachers to be the critical pedagogues in charge. This stance requires teachers to be the critical agents who led the curricular planning and instructional decision-making because they can be the more responsive within the complex and dynamic system that exists in STEM classrooms ([Darling-Hammond, 2006](#)).

Design-based pedagogy

One of the major goals that contributed to forming our research endeavor was to support teachers with design-based pedagogies in the context of integrating LEGO robotics and engineering when planning math and science lessons, developing instruction strategies, and becoming a stake-holder in their own professional learning. One of our key epistemological standpoints for design-based pedagogy is that teachers are stakeholders at every step of the pedagogical decision making process. Now, that does not mean that teachers are learning solely on their own. Rather, we found success in fostering teacher professional learning by positioning teachers, mathematics and science education researchers, and engineers as “design-partners” ([Devitt et al., 2018](#)). Each partner brought her or his personal areas of expertise, whether from experience, scholarship, or both, and contributed to the shared activities and purpose of developing math and science lessons that integrated LEGO robotics for middle school classrooms.

Over the course of a three-week professional development workshop, as teacher educators, we provided instruction on various learning theories and collaborated with middle school teachers on their on-going lesson planning to develop a sense in how to use new pedagogy to inform the lesson planning and instructional practice. We drew from the work on problem-based learning ([Kolodner et al., 2003](#)) and Technological Pedagogical Content Knowledge (TPACK) ([Mishra and Koehler, 2006](#)) in order to conceptualize how to design purposeful and authentic ways for using technology to enhance their math and science lessons. We explicitly wanted to avoid using technology as a flashy gimmick that provides entertainment but overshadows any learning of mathematics or science conceptual development—as found in the research of [Norton et al. \(2007\)](#). We drew from the work of Jean Lave on “situated learning” (1988). We provided learner-centered perspectives for designing engagement activities in mathematics and science lessons. A new phrase we integrated was how to reason *with context* and not just *in context* ([Lave, 1988](#)). In our professional development LEGO robots provided the context from which we developed mathematics and science lessons.

In order to analyze the intellectual contributions of teachers to their lesson planning and the artistic maneuvering when implementing their science and mathematics lessons, we adopted, and adapted, Donald Schön's (1983) model where he conceptualized teaching as a “professional practice”. One of the central tenants we adopted from Schön (1983) is that teachers need to be part of the “problem setting” stage. We interpret this to mean that, rather than having curriculum developers decide what is important to teach and subsequently providing pre-designed lesson plans and activities, the teachers need to be positioned from the start to take national and state standards, decide how best to translate the purpose in their given setting and to their specific audiences, and develop appropriate activities and instructional strategies to support learning. Schön (1983) sets forth a cogent heuristic for analyzing the professional work of teachers to illuminate, understand their overarching purpose (problem space), make curricular and instructional decisions based on their professional knowledge of their students and relevant social, political, or environment issues within which to couch the lessons (reframing the problem), and continuously monitor and make necessary, micro-level pedagogical changes if and as needed (experimenting and evaluating).

Within design-based pedagogy, we have developed guideposts on Schön's seminal book, *The Reflective Practitioner* (1983) to articulate the work of teachers as professional practice. We have found that it is both formative to help teachers construct science lessons as well as a useful analytical tool to recognize teachers' professional practice in times of action and reflection. Schön's (1983) three central guideposts include:

- (1) Identifying the problem space: Schön's first step of professional practice is to have teachers frame the initial problem. The “problem” is the ability to conceptualize or outline the dimensions of a theoretical space in which to enact pedagogical decisions. For teachers, this often means conceptualizing the depth and objectives stemming from national and state standards within their discipline. Within our professional development, teachers framed the problem space, for example about how to integrate LEGO robots into their science lessons.
- (2) Reframing the problem: Schön's second step of professional practice requires teachers to take on the task of reconceptualizing the problem space as a real-world, authentic issue that is contextualize for the purpose and relevance of her students' lived-

experiences and strengths—based on recommendations from problem-based learning (Kolodner et al., 2003). Also, teachers need to consider what lessons came before and what is coming in the future to maintain coherence in the curriculum.

- (3) **Experimenting and Evaluating:** The third guide post refers to how teachers put their pedagogical decision-making into practice. Teachers are tasked to continuously monitor and evaluate the quality of learning as the lesson unfolds. Teachers can make micro-level adjustments to the curriculum or in their instructional practice. These might look like teachers providing explanations of the context, prompting or probing students, assisting with the technology, etc. Based on what is learned from teaching the lessons, teachers refine what practices could be used in future iterations of science lessons (Barab and Squire, 2004).

In order to make the professional-level decisions, teachers utilize practices such as “reflection-in-action” and “reflection-on-action” and listen to how the teaching situations “talk back” (Schön, 1983). It is important to note that Schön (1983) comes from a phenomenological perspective and takes the stance that professional knowledge exercised in both technical critique and embodied practice—but placing extra emphasis on embodied decision making when it comes to in-the-moment pedagogical changes (Schön, 1983). Given the complex, dynamic, and contextual nature of teachers’ professional work, Schön’s (1983) model for professional practice has been instrumental for helping analyze, understand, and make the importance of the “intellectual” work of teachers. From these guideposts, we highlight the elements of how teachers and their “design partners” engage in the design-based pedagogy (see Fig. 1).

Lesson planning as design partners

As described earlier, teachers are best positioned to engage in the design process of developing and implementing science lessons when they are key stakeholders and designers from the initial conceptualization and planning stages. Design-based science lessons require goal-based, real-world scenarios for students to work toward (Schank et al., 1994). In our professional development project, LEGO robots played a key role. We advise that technology be utilized in a way that enhances the lesson, and not just become a “bell and whistle” engagement strategy. Technology integration ought to help students nuance the way in which they interact with the phenomena. New disciplinary ideas, tools, and terminology should be weaved into the lessons so that students capture the use and purpose within the context to foster scientific engagement and thinking (Vygotsky, 1978). Lessons should include multiple opportunities for students to interact with phenomena, plan and conduct investigations, and produce a meaningful artifact that can be shared or even kept (Papert and Harel, 1991). The artifact can be used to help communicate what they learned and how they developed their ideas throughout the process.

Teacher educators and researchers can help foster teachers’ abilities to develop these kinds of lessons as “design partners”. Rather than provide examples or pre-prepared curriculum, “design-partners” collaborate side-by-side to devise lessons at each step of the way. Together, “design-partners” examine state and national standards, choose relevant, real-world problems to reframe performance expectations or learning objectives. When teachers were provided an opportunity to collaborate and plan their lessons. They started by asking reflective questions: “what do we use as our resources” and “what do students need to know”? They used the Next Generation Science Standards (NGSS) as a starting point to construct their problem space. As part of the “reframing” process, one group of teachers devised an original scenario:

You are living in the year of 2150. Families are no longer required to make weekly visits to the grocery stores. The EV3 ShopNOW robot service provides families with home delivery. Three families have sent lists for groceries to be delivered. However, some robots are malfunctioning. The EV3 robots has encountered a defect that results in robots crashing into the cashier register. A force of 300 N or more will cause injury to the cashier. Your task is to investigate which cart mass will produce a force that the cashier can stop.

Fig. 1 Initial elements of design-based pedagogy.

Researchers on the project collaborated as “design-partners” to help revise the scenario. Together they co-constructed:

Right now companies are manufacturing and currently testing in local markets around the world—robots that can deliver up to three shopping bags' worth of goods within 30 min to homes within a 3-mile radius. The company, according to CEO Heinla, is “reinventing” the so-called last mile of transportation, and it's currently running tests with commercial partners such as London's takeout food delivery service Just Eats that involves the robots ferrying meals to customers. However, one of the challenges is making sure that the robot which collects the grocery items does not crash into the register. Your challenge is to explore the level of force involved and decide what is a safe level for the cashier.

The goal of revising the scenario was to make it as authentic to real-life as possible. First, we want science lessons to be realistic in the sense that the scenario actually occurs, or could happen, in the real life of students. In this scenario, we helped teachers conduct a Google search and select an example that exists in the real-world. Second, we wanted to maintain accountability to the agency of the phenomena. In this example, we helped teachers more accurately re-conceptualize the problem of how robots cause injury to cashiers, in order to make it more realistic. According to [discover.com](#), an article highlights that it takes about 4000 N to break a human leg. Therefore, 300 N as the original scenario was written, would not have accurately represented the phenomena of force and human injury. As design-partners, we helped teachers better understand that mathematical and science learning is more than just solving equations and problems, but also to help students learn about how to use equations and problem solving to better understand real life phenomena (Devitt et al., 2018).

Implementing science lessons for ELLs and students with disabilities

We learned that teacher professional practice is a complex and dynamic social phenomenon that is difficult to understand from the outside. As part of the professional development, after teachers taught science lessons that were designed during the summer workshops, we held follow-up reflective sessions. During these sessions, teachers shared stories and videos of how they implemented their lessons, highlighted strengths and challenges, and explained what they learned from engaging in the process. We found that using our framework of design-based pedagogy and the guideposts set out by Schön (1983), we were able to analyze teacher stories in ways that illuminated the multi-faceted layers of teachers' professional decision-making and evaluation. This was particularly fruitful to help us better understand how teachers implemented and refined their lessons. In particular, while hearing teacher stories, we were most interested in the parts where teacher moves and outcomes were discussed.

In Table 1, there is a list of quotes pulled out from a story told by Ms. Chang, a middle school science teacher who teaches in an area of New York City with high populations of Chinese-speaking students. She explained that she taught a lesson using the LEGO robots focusing on planets in the solar system. She showed a picture of a PowerPoint slide that had directions in both English and Chinese. Ms. Chang said, “*I translate the worksheet from English to Chinese so that my students can read. The only barrier for them to learn (science) is the language, otherwise they are super smart kids*”. Ms. Chang's story revealed that she modified her lesson to include Chinese characters to help students who struggle with the English language access the directions and lesson content. She implied that this was the only modification needed for her lesson as students were able to demonstrate learning once language barriers were removed.

In Table 2, there is a list of quotes pulled out from a story told by Mr. Wilson, a middle school science and special education teacher whose class consisted of 12 students with Individual Education Programs (IEPs). Within his story, he shares how he problematizes teaching about the solar system, while also considering the individual needs of students with disabilities who were in multiple grade-levels. He reframes the problem for discussing a specific lesson where he considered how to best use the LEGO robots. He planned for merging students' previous experiences with positive and negative integers and how to build on using computer programming (Scratch) to teach the concept of using “x and y” in a coordinate system. Mr. Wilson shared a multitude of strategies he tried in order to support student learning. For example, he practiced the coordinate system using 3D printing, he invited previous students back to his classroom to act as leaders and mentors to current students, and he allowed students to use the hallway to increase the space in which students can model the solar system. He evaluated the outcomes of his adjustments by saying that he was further along in the curriculum than previous years, he noticed that students have a “light go off”—indicating that students recognize their own “ah-ha” moments, and that students are engaged in quality scientific conversations.

Table 1 Example analysis of a middle school science teacher of English Language Learners.

The problem space	● How I get the lesson (cell cycle) is from the Google Drive ● I aligned the lesson to the scope and sequence. The cell cycle I learned from the last professional development [meeting].
Reframing the situation	● [Presented on PowerPoint slide] lab: Understanding the length of each phase of the cell cycle actual model. ● I translate the worksheet so my students can read.
Experimenting and evaluating	● The only barrier for them to learn is the language, otherwise they are super smart kids.

Table 2 Example analysis of a middle school science teacher of students with IEPs.

The problem space	● This year I was fortunate to have five, 12-to-1-to-1, configuration (i.e., 12 students with IEPs, one special education teacher and one paraprofessional). ● All the kids have IEPs with various disabilities. All my classes are mixed grades: sixth and seventh or seventh and eighth but also on second or third grade reading level. ● Focus on lessons on the solar system [PowerPoint slide title] ● There is such an interaction with whatever I use in the classroom, that there are hooks in and out of the program. I Look to hook them however I can so that they want to come to class so that they want to do whatever we are doing on that day.
Reframing the situation	● Although I'm teaching science, I have done work on positive and negative integers to get them comfortable. ● Because I'm using scratch [programming]—so the kids realize that there's an x and y thing happening, and if I can demonstrate that happening on the floor—that's a visualization of a concept that is somewhat difficult for them.
Experimenting and evaluating	● Students are doing two things: we started printing thing out on the 3D printer. The kids have to use TinkerCad. So they use 3D cadcam printing software, which is based on X,Y coordinates and they are printing off planets and putting them onto the robots. ● So we're using kids to come in a mentor other kids and we all know that kids learn best from each other. ● One of the other things I have done here, this is my second year here using the robots. I've developed leaders, I bring students from different classes in if I need a particular thing accomplished for that day. I've introduced programming for instance. So I have a couple of seventh and eighth graders—girls by the way—that come in and teach my sixth and seventh graders how to program. We will do, some time after the break: graphs. ● I bring the student programmer in and she helps them to understand how we can do this, how we can make it [the robot revolve] faster, how we can change the power, how we can change the wheel size—now we're talking about circumference, and radius, and diameter, there are formulas involved and I have students mentoring other students. ● We're further along this year than we were last year and I think that at least has something to do with my familiarity with things (i.e., robotics, programming—this was this teacher's second year in the program) and my willingness to trust the students—and I have some students who are working with me for a second year in a row. ● Now I have a team in the hallway and last year I could not let three kids in the hallway. ● At some point the light goes on after really accomplishing something. ● Now what they want to do is put a broomstick in the center and run all nine planets. Is it a true analysis of spherical rotations? Not at all, but if I get kids to have that level of conversations, it's a homerun.

The goal of highlighting two examples of how teachers implement science lessons is not to compare the quality of teaching. The purpose is to highlight that when teachers are positioned to develop their own lessons, they are capable and effective at making necessary adjustments to their curriculum and instructional practices as needed to the point where students more fully participate in the flow of the lesson and are able to demonstrate learning. Since the teachers selected the learning goals and subsequently developed the lessons, they were able to make the intellectual verifications of what quality science learning looked like, and subsequently connect their own successes to the adjustments they made to their curriculum and instruction. When teachers implement pre-packaged lessons with fidelity, the onus of learning often shifts to the full responsibility of the student. Failure is often attributed to deficiencies in student intellect, motivation, behavior, or other personal dispositions rather than assuming that the curriculum or instructional practices need adjustments. Design-based pedagogy enables teachers to better support and ensure the learning of our most marginalized students (Devitt et al., 2019a,b).

Integrating robotics in ways to enhance professional learning

Stories that teachers shared also revealed how teachers began to improve the quality of technological integration in ways that advanced students' development of conceptual understanding (Devitt, 2020). Alisha, a middle school math teacher described how she typically used the city-wide adopted mathematics curriculum for teaching her course. When teaching the concept: adding and subtracting positive and negative integers, she historically used number lines to demonstrate mathematical problems. Then, in light of learning how to use the LEGO robots and programming during the summer workshop, she wanted to plan a lesson that engaged students to think algebraically by using "in-and-out machines" or "in-and-out tables" in order to demonstrate the relationship between numbers and functions. She shared that by using the LEGO robot she could teach her sixth graders how to use higher grade-level mathematical tools (i.e., functions). Rather than having students use number lines, the robots could be programmed with functions and students could input numbers into the robot which would act as the "in-and-out machine"—and move according to the programmed function. Alisha expressed that students could reflexively engage in thinking about: *"What is it that the machine's doing to the number? What is happening mathematically?"* Alisha explained why the robots were so valuable to her nuanced way of teaching numbers and functions. She said, *"I think maybe just seeing visually how they [the robots] move along the number line I think it really clarified the error of, you know, you can count the numbers along the number line, as opposed to the jumps and the physical movement of the robot. And how that clarified it for them"*. In other words, students might make errors when using a numberline to practice the functions and not notice if they make mistakes. However, when the robot is programmed and students input numbers, students' expectations of where the robot should end up and where the robot ultimately ends up causes students to clarify their errors of thinking (Devitt, 2020).

Conclusion

In addition to conceptualizing teachers as “intellectuals” and “design partners” in the service of producing quality science and mathematics lessons while integrating robotics, with the design-based pedagogy model, we position teachers as agents in forwarding their professional practice. Two major goals are achieved when STEM teachers engage in professional practice that is reflective of the design-based pedagogy set forth in this book chapter. First, teachers produce high-quality STEM lessons that capitalize on integrating robotics and engineering. Because teachers are involved and invested in the construction of the entire lesson; including the planning, institutional design and implementation, and reflection on the overall process, they have the know-how to make micro-level adjustments as needed to support student learning and have full knowledge of the landscape from which to further their future lessons—key for promoting and developing professional practice. Second, as teachers have sound contextual understanding of the schools, community, and students’ needs and strengths, they are the most knowledgeable and positioned persons for designing the curricular and instructional practice for whole classes, and make the micro-level adjustments (i.e., prompts, probes, assists, etc.) for individual students. This pedagogy is especially promising for teachers to be most responsive to the quality and individualized education for English language learners and students with disabilities. It is my firm belief that we need to prepare teachers to develop pedagogical practice that best supports students on the margins from the ground up rather than start with a pre-packaged curriculum that needs to be “differentiated” for students who do not fit the intended mold.

Introduction: the STEM learning gap

The prevalence of and accelerating innovations in technology are transforming everyday human experiences. There has been a growing reliance on technology to facilitate and ease our daily activities, including healthcare, education, leisure, etc. Furthermore, COVID-19 pandemic has catalyzed the digital transformation and altered our perceptions about online channels for almost all the industries. The ever-changing nature of work, predictions about the future of work, and rapid proliferation of technology call for an increase in skilled Science, Technology, Engineering, and Mathematics (STEM) workforce. Unfortunately, the US education system is facing a substantial challenge in generating adequate numbers of qualified STEM professionals who can fulfill the demands of the future workforce. A closer look into the STEM pipeline reveals that only 20% of country's high school graduates are equipped to handle STEM education and a mere 10% of global science and engineering graduates are from the US (Herman, 2019). These dismal statistics indicate a major need to intervene and support schools, teachers, and students to acquire professional skills that contribute to STEM learning and a better-prepared workforce.

One barrier to a well-prepared STEM workforce stems from the lack of interest and perceived value of STEM learning among students. Even though students are exposed to a variety of technologies in their day-to-day activities, their STEM educational experiences fail in intentional use of modern technologies (Iskander et al., 2010). This lack of exposure to contemporary technologies in a learning context disengages learners from STEM disciplines. Moreover, it denies them meaningful experiences to hone professional skills relevant to a modern and technological workplace (Sobhan et al., 2007). Even as the interdisciplinary nature of STEM fields is widely recognized, students continue to receive siloed exposure to disciplinary content knowledge in STEM. Furthermore, a majority of students find it challenging to understand STEM concepts in an abstract manner and fail to see their real-world implications. This prevents them from deeply understanding the STEM topics and, thus, finding value in it. Unfortunately, 30% of students lose interest in science disciplines by grade 4 and nearly 50% of students lose interest in pursuing STEM careers by grade 8 (Hurst et al., 2019). Thus, most of the students disengage from STEM fields by their high school years.

Teacher knowledge and abilities are known to directly influence the achievement of students (Sanders and Rivers, 1996). Thus, it is paramount to have teachers who feel comfortable with and have the capacity for technology-enabled instruction so that students can be equipped to attain success in STEM disciplines. Yet, most teachers lack sufficient preparation in integrating STEM content in their lessons and find it challenging to adapt, contextualize, and demonstrate the use of contemporary technologies in their classrooms (Chen et al., 2009; Ottenbreit-Leftwich et al., 2018). Furthermore, it can be challenging for teachers to stay updated with the advancing hardware and software of these technologies (You and Kapila, 2017). This results in classrooms that are less engaging, accessible, and personally relevant to students (AeA, 2005). Teachers' lack of preparation can also result in absence of familiarity and knowledge of advanced technologies among them, which may, in turn, affect their self-efficacy.

It is pivotal to address the aforementioned barriers to student engagement and teacher preparation in STEM to meet academic demands of today's learners and for their career success. To generate enthusiasm and engagement among students in pursuing STEM fields, the curricula must incorporate modern and familiar technologies (Benitti, 2012; Riojas et al., 2011), be personally and culturally appropriate (Young et al., 2019), and embed real-life applications in students' own communities (Morales-Doyle, 2018). The STEM programs must invite students from early ages through developmentally appropriate and hands-on activities that build familiarity and promote knowledge development among learners. Moreover, professional development programs must empower teachers in developing comfort with modern technologies and promote technology-infused learning for their hands-on practice.

Rationale for incorporating mechatronics and robotics with entrepreneurship experiences in classrooms

The last few years have witnessed a noteworthy increase in the use of robotics for designing transformative interdisciplinary learning experiences (Alimisis, 2013). The emerging field where robots contribute toward development of learners' skills and competencies is called Educational Robotics (Eguchi, 2012). Robotics, for the purposes of teaching and learning, has been primarily introduced to develop learners' interest and involve them in topics that are challenging to teach via traditional methods (Whitman and Wither-spoon, 2003). Educational robotics fosters deeper understanding of concepts through hands-on, active engagement that gives learners the opportunities to collaborate and solve complex problems (Mosley and Kline, 2006). On the other hand, mechatronics, which is the synergistic integration of mechanical engineering, control theory, computer science, and electronics to manage complexity, uncertainty, and communication in engineered systems (Kapila and Lee, 2004), can also ignite the intellectual curiosity of participants and empower them to perform hands-on STEM learning, conduct engineering research, and foray into entrepreneurial explorations. Multiple studies have revealed that students who engaged in such a learning showed positive learning outcomes (Hartmann et al., 2007; Milto et al., 2002; Rusk et al., 2008). Among the myriad advantages of deploying mechatronics and robotics in classrooms, some are highlighted below.

- These disciplines are well suited for project-based explorations wherein participants learn about the course material and engage in critical thinking while solving problems, contextualized in a facilitated design project, that may entail multiple solutions (Barron et al., 1998).
- Mechatronics and robotics generate an authentic learning environment through real-world problem solving where students make connections between various STEM concepts, build their own knowledge, and showcase their learning (Eguchi, 2012). Such a learning is limited not just to STEM-based topics but is applicable to other disciplines including social science, literacy, etc. (Rahman et al., 2017).
- Robotics-enhanced experiences engender student-led learning that is relevant to them. Such a hands-on learning of abstract topics engages students, infuses enthusiasm in them, and motivates them to present their work (Brill et al., 2016).
- The interdisciplinary and active nature of robotics-based activities cultivates 21st century professional skills and computational thinking skills among learners (Rahman et al., 2018). Such a learning gives students multiple opportunities to collaborate and brainstorm on challenging problems and affords opportunities to iterate on their solutions (Eguchi, 2021).
- Educational robotics makes learning equitable and accessible to all learners. The hands-on exposure to STEM concepts is crucial in developing cognitive and social skills among learners (Alimisis, 2013) and, thus, is a critical contributor in bridging the STEM learning gap.

Even though robotics-based learning offers a compelling approach to engender deep understanding of concepts, its classroom adoption is often limited to robotic design and programming (Williams et al., 2011). Most programs fail to utilize robotics to its fullest potential by using it as a passive learning tool (Ghosh et al., 2020) or employing it for extra-curricular activities (Williams et al., 2012). This limited exposure to the foundational concepts of using technological artifacts can impact students' understanding and deter them from entering the STEM fields. Moreover, a well-informed and prepared STEM workforce requires students to not only have STEM content knowledge but to also be adequately equipped in the entrepreneurial landscape. Today's technology-driven entrepreneurial landscape calls for a large number of entrepreneur-engineers who are equipped to generate novel products for the innovation economy, especially due to a complete transformation of the technology landscape since the pandemic. The project team believes in the prospect of emergence of novel entrepreneurial ventures through the technological affordances of mechatronics and robotics.

The infusion of educational robotics and technology-based entrepreneurial innovations can be utilized to impact students' abilities, interest, and awareness in STEM disciplines and careers. When students are exposed to STEM fundamentals through mechatronics and robotics integrated with business and communication skills, they can envision concrete applications of their STEM

knowledge and skills. Research has shown positive impact of entrepreneurship-based education programs to increase learners' self-efficacy, persistence, creativity, and desire toward entrepreneurial careers (Beary, 2013; Cioffi et al., 2014). Moreover, mechatronics and robotics are still nascent disciplines that have the promise to solve varied problems and advance into successful entrepreneurial solutions. Mechatronics- and robotics-based designs can render experiences in systems integration and product development which can support learners in honing and implementing their creativity, innovation skills, and entrepreneurial mindset. Leveraging students' fascination toward robots, devising real-world simulations, and designing an entrepreneurial experience can be an effective approach for learners to envision themselves as contributors to the future STEM workforce.

Overview, theoretical background, and design of the project

The necessity to develop pedagogically-sound learning experiences in mechatronics and robotics, and integrate them with entrepreneurship, led to the design and implementation of research-informed teacher professional development workshops. The workshops sought to create for teachers a motivational and engaging program that includes mechatronics and robotics training; immersion in hands-on, collaborative research; opportunities to cultivate entrepreneurial skills; and interactions with industry engineers. To address the STEM learning gap, the following key activities were included in the summer workshops of six-week duration.

- Introduce the interdisciplinary fields of mechatronics and robotics to teachers for renewing their knowledge and skills in science, math, and research. To do so, the workshop created a structured and integrated learning environment consisting of training, mentoring, and real-world collaborative engineering research.
- Provide teachers with hands-on experiences, skills, and resources in engineering research, prototype product development, entrepreneurship, and professional engineering practices. Such an approach can prepare teachers to: integrate project-based learning in their science and math curriculum; enhance school labs with technology used by scientists and engineers; improve their communication, presentation, and business skills; and inspire their students, through examples of real-world applications, to pursue careers in STEM and create technology ventures.
- Conduct a student idea competition and create a high school summer internship program.
- Enable undergraduate and graduate engineering researchers to develop communication, leadership, and mentorship skills; a deeper appreciation of STEM teaching and learning; and contribute to the research on K-12 STEM teaching and learning.
- Enable project team to integrate their research, teaching, and curriculum and lab development efforts with K-12 education activities.

The six-weeklong summer professional development workshops and ongoing academic year support were founded on credible theoretical frameworks of project-based learning (PBL), robotics-based teacher professional development, 5E instructional model, and learning standards alignment. This novel intersection builds on the affordances of real-world applications of mechatronics, robotics, and entrepreneurship, and thus is valuable in positively shaping teacher preparation. The project incorporates a variety of thoughtfully conceptualized hands-on activities (see **Project design and activities** subsection) that culminate into a showcase of student projects through an entrepreneurial idea pitch competition. This work-based environment (Lave and Wenger, 1991) facilitates the accumulation of diverse experiences, familiarization with contemporary industry practices, and insight into disciplinary knowledge, all of which eventually translate into effective student learning. Thus, during the workshop, teachers were given opportunities to interact with professional engineers through industry site-visits and mentorship to enhance their practical knowledge of STEM disciplines. Under cognitive apprenticeship (Collins, 1991), such an experience allowed teachers to model the gained skills for students, improving their understanding of STEM topics as well as awareness of STEM pathways. Over the duration of 3 years, the workshops and academic year activities were attended by 30 teachers who were hosted by the faculty, researchers, and engineering graduate students at an engineering institution in North East US. A description of the theoretical background and project design are provided in the following subsections.

Theoretical background

To generate purposeful and engaging hands-on experiences, we utilized the interactions of mechatronics, entrepreneurship, and industry experiences grounded in the theoretical frameworks of PBL, robotics-based teacher professional development, 5E instructional model, and learning standards alignment. A brief review of the theoretical frameworks is provided below.

Project-based learning

PBL is an instructional approach where learners investigate or solve a challenge over a sustained duration of time and, in the process, acquire intended knowledge and skills. PBL promotes critical thinking, collaboration, enhanced understanding of concepts, and long-term retention of content (Melchior et al., 2004) and, thus, is well suited for integration with mechatronics and robotics. Such a learning renders opportunities for authentic problem solving (Eguchi, 2012) and inspires self-reflection. Instantaneous feedback in the form of mechatronics device performance or robot behavior can give students opportunities to iterate and revise their solution and, thus, engender an atmosphere for self-directed learning (Eguchi, 2012). Furthermore, the learning artifact designed via collaborative team efforts is shareable among a larger community (Carbonaro et al., 2004) and is an effective means to instill a sense of purpose in learners. While the improved STEM knowledge can aid students in developing their own products, their lack of

entrepreneurial knowledge may limit it from reaching the intended market. This necessitates the integration of entrepreneurship in the curriculum. Relevant project-based mechatronics and robotics experiences combined with business skills can empower students to envision real-world applications of the generated STEM knowledge, which, in turn, can help foster confidence and creativity among learners. In this effort, PBL was an integral part in the design and development of learning activities that sought to imbue intellectual curiosity through socially relevant problem-solving.

Robotics-based teacher professional development

Professional development is crucial in addressing the evolving needs of teachers' content knowledge, skill improvement, and building their confidence (Desimone, 2011). The ongoing advancement of technology and its integration in the process of teaching and learning has further necessitated concentrated efforts toward teacher upskilling (You and Kapila, 2017) as the complexities of such tools can make teachers reluctant in employing them in their classrooms (Moorhead et al., 2016). Professional development programs need to be designed to focus on pedagogical aspects of technology integration as opposed to using technology tools for administrative tasks (You and Kapila, 2017). Robotics-based professional development programs, specifically, must address teacher needs; generate familiarity and comfort in using robotics tools; support them in connecting robotic activities to curriculum (Norton et al., 2007); and build their skills, knowledge, and beliefs. Such programs must allow teachers to engage in hands-on explorations using the robotics tools to solve real-world problems that may be personally relevant to their students. Moreover, high-quality and effective professional development programs must last for sufficient duration of time, involve collective participation, endow active learning experiences, and be coherent in their design (Garet et al., 2001). For instance, effective professional development programs must move away from short, one-shot models that assume a passive role of teachers to more hands-on and constructivist learning models (Sparks, 2002; Harada, 2016). The plan and design of the workshops must adhere to curricular and learning standards (Allen and Penuel, 2015), be cognizant of students' cultures (Gay and Howard, 2000), and extend for a sufficient duration of time (Sparks, 2002). This effort was founded on a strong and structured professional development program that lasted for six weeks. Under the PBL framework, the participants were provided hands-on learning experiences, guided training, collaborative research work, and industry experiences. Moreover, teachers were periodically visited in their schools during the academic year to support their in-class and after-school activities that built on the summer workshop.

5E instructional model

The 5E instructional model, consisting of the Engage, Explore, Explain, Elaborate, and Evaluate components, is a pedagogical approach that aims to develop higher order thinking skills and render a conceptual change in the learners (Tanner, 2010). Through a structured and well-organized sequencing of its components, the 5E model allows the learners to surface their pre-conceptions, explore novel ways of approaching a problem, learn new concepts deeply, apply their learning to various situations, and evaluate their understanding (Tanner, 2010). The model is widely accepted for developing curriculum, planning lessons, designing teacher professional development programs, or designing informal learning experiences (Bybee et al., 2016). The adoption of 5E framework with fidelity can lead to improvement in student learning, motivation, and retention of concepts (Bybee et al., 2016). The 5E framework can work effectively in tandem with the Next Generation Science Standards by rendering lessons that incorporate engaging scientific practices, exploring research questions, conducting engineering design research, evaluating the results of new phenomena, etc. The 5E model addressing the learning dimensions of NGSS was a key component of this effort as it offered teachers a pragmatic methodology through a manageable and scientific sequence. Embedding such learning experiences in the classrooms can enable students to develop an appreciation for the new concepts through observation, inquiry, and analysis.

Next Generation Science Standards (NGSS)—alignment with teacher professional development program and 5E instructional model

The NGSS were devised to develop new ways of thinking and learning in STEM disciplines by alleviating the prevalent challenges of siloed focus on developing science content expertise and inadequate illustration of interconnections between the concepts. Organized in a unique three-dimensional format, the NGSS reimagined K-12 science in a model consisting of Disciplinary Core Ideas (DCI), Cross Cutting Concepts (CCC), and Science and Engineering Practices (SEP). DCI consist of science concepts and ideas students must learn, CCC are pervasive across subfields within science and allow students to apply their learning, and SEP are activities that help students understand the development of scientific knowledge and forms linkages between science and engineering (Bybee, 2014; Duncan and Cavera, 2015). The NGSS afford teachers with opportunities to flexibly envision, design, and enact novel lessons that prepare students for post-secondary education (Moore et al., 2015) and allow students to explore the real-world through the lens of scientists and engineers (Moore et al., 2015). Effective adoption of NGSS requires large-scale professional development programs to enable teachers to transition away from the old science standards (Wilson, 2013). Thus, programs that prepare teachers to understand and employ the NGSS are critical. This project's professional development program exposed participant teachers to effectively learn and apply the NGSS framework for addressing the challenge of designing standards-aligned curricula, instruction, and experiential learning. Moreover, the participating teachers received feedback and support from their peers and project team in improving their lesson and its enactment. The NGSS were integrated with the 5E framework for optimal exploration of scientific concepts that would expose learners to interconnected knowledge structures. Furthermore, this NGSS-plus-5E professional development workshop gave educators autonomy and flexibility to ideate, design, and implement novel lessons in classrooms.

Project design and activities

To maximize the learning potential using mechatronics, robotics, and entrepreneurship experiences, the summer workshop employed a scaffolded approach that included a two-weeklong “guided training” and a four-week “collaborative research” experience. Such an approach was deliberately followed to instill a level of confidence among teachers to engage with mechatronics and robotics technologies and research. Teachers also participated in a “lesson development workshop” on three days during the six-week professional development (one day every two weeks), that focused on aligning lessons to NGSS and 5E instructional model. Moreover, they gained familiarity with the “real-life experiences of industry professionals” through workshops or presentations by them as well as industry site visits. See Fig. 1 that illustrates teachers engaged in the diverse activities of the project. During the academic year, project team members periodically supported teachers as they implemented mechatronics and robotics-based lessons and activities. Students from teachers’ classrooms participated in a business idea competition that encouraged them to pitch economically viable technology solutions for real-world challenges.

The program started with an orientation and interaction between participating teachers and project team members. Teachers were also provided with the program agenda, demos of sample projects from earlier offerings, lab safety instructions, and a mechatronics and robotics learning kit composed of components, supplies, and study material. Following are details of the program elements.

Guided training

The first two-weeks of summer workshop involved guided training sessions that introduced teachers to the fundamentals of mechatronics and robotics (sensors, actuators, electronics, electro-mechanical components, microcontrollers, etc.) and entrepreneurship. Each day was divided into morning and afternoon sessions where teachers participated in interactive lectures, corresponding hands-on experiments, and discussions on classroom implementation of their learnings. Sessions on entrepreneurship included key concepts on assessment of business opportunities; strategies for managing financial, human, and technology resources; networking; business promotion; and sustainable growth. Teachers were divided in small groups during these sessions and provided opportunities to design their innovations, create their venture ideas, examine successful business models, and engage in networking. Experience of every small success, by themselves or by their peers, in myriad hands-on learning activities of guided training prepared teachers for collaborative research in mechatronics and robotics.

Collaborative research

Following the guided training, for the next four weeks, teachers experienced the process and challenge of conducting authentic engineering research by working individually or in teams, through project-based learning. They contributed to ongoing research projects

Fig. 1 Workshop participants: (A) conducting hands-on learning activities during guided training; (B) discussing their research; (C) visiting a startup robotics company; and (D) attending a robotics workshop by an industry professional.

involving graduate, undergraduate, and high school researchers, and faculty members in four different laboratories, i.e., dynamical systems, bioengineering, mechatronics, and robotics labs. These collaborations afforded the opportunity for teachers to observe how research is conducted and it allowed them to enact their newly acquired knowledge and skills from the guided training. They had ample opportunities to employ their learnings in authentic research settings while practicing the skills of communication, research, and teamwork.

Lesson plan development workshop

By participating in an NGSS-plus-5E lesson plan development workshop (for three days during the six-week period), teachers explored the 5E instructional model with the three-dimensional model of NGSS. This was done to allow the teachers to utilize their laboratory experiences from collaborative research to develop lesson plans grounded in the NGSS and 5E frameworks. The teachers first had an opportunity to support a group of teachers from another program by attending their lessons as students and providing them with feedback to improve lesson designs. In this process, they acquired skills to develop their own NGSS-plus-5E lesson designs. Attending these workshops also allowed the teachers to experience the real-world enactment of NGSS through the process of understanding how to approach research questions and examine the role of three dimensions (CCC, DCI, and SEP) in addressing these questions. They could transfer this learning from the workshop to their collaborative research, ensuring learning of research concepts. Following the workshop, teachers designed several novel lesson plans drawing knowledge from their research collaborations, i.e., the underlying concepts of research projects informed the NGSS-grounded lesson designs. For instance, a two teacher team conducted research on designing a user-friendly smartphone app to control a robotic car. The app consisted of various features that permit users to command the robot in a natural and intuitive manner with minimal effort. An Arduino microcontroller and a breadboard populated with required electronic and sensing components made up the control system hardware interfaced to the robotic car. Using the same principles of microcontrollers, electronics, sensing, programming, and a simple smartphone app, the teachers created a lesson plan that encouraged students to learn, develop, and apply their engineering skills to create a working windmill. The lesson embeds opportunities for students to improve their design to increase the windmill energy output (see [Table A.I](#), [Appendix A](#), for a detailed lesson plan). Another teacher collaborated on a research project to develop a rehabilitation system to monitor finger grip force for stroke patients. This system used a force sensor, a webcam, a rehabilitation device, all interfaced with an Arduino microcontroller, Unity game engine (for a user-friendly set up), and a machine learning algorithm to accurately measure the grip functionality of hand and arm movement. Equipped with her new understanding of force sensors, Arduino, and Unity gaming, the teacher created a lesson that encourages students to design different types of bridges and strategically mount force sensors to monitor the amount of load. The lesson is facilitated through examples of real bridge collapses, which can allow students to explore various causes that may lead to bridge failures (see [Table A.II](#), [Appendix A](#), for a detailed lesson plan).

Industry-based experiences

During the four weeks of collaborative research phase, teachers participated in workshops and talks by industry partners as well as informational visits to technology startup and industry sites. This afforded teachers with additional insights into industry operations and ability to associate practice with theory and *vice versa*. The visits provided teachers with exposure to startups, research facilities, and technology consulting companies that focused on generating a wide variety of engineering solutions. For instance, teachers visited: (i) a robotics-plus-virtual reality startup that supports real-estate marketing companies by creating 360 degree virtual walk-throughs; (ii) a physical rehabilitation research facility that is engineering and evaluating cutting-edge technologies for motor recovery; (iii) a research and development company that conducts innovative robotics engineering projects for several federal agencies; and (iv) a technology consulting startup of a graduate of the host engineering school. A two-day hands-on robotics workshop was conducted by an educational robotics company that allowed teachers to build and program a robot using a block-based programming interface. Moreover, a one-day hands-on microcontroller workshop was conducted by another educational electronics vendor that allowed teachers to interface a Micro:Bit device with a variety of components for their monitoring and control.

Classroom implementation support and academic year activities

After the six-weeklong summer professional development workshop, teachers enacted their NGSS and 5E aligned STEM lessons in classrooms or newly developed robotics clubs. Project faculty members and graduate researchers collaborated with and supported the teachers in planning and organizing their robotics activities. Graduate researchers' presence also allowed students participating in the mechatronics- or robotics-based business idea competition to consult and improve their engineering design and be more successful in such activities. Additionally, under the cognitive apprenticeship model ([Collins, 1991](#)), graduate researchers shared their research and professional experiences in STEM with the students. This rendered an opportunity for students to interact with researchers and learn more about STEM career pathways. Teachers sought to create and conduct varied activities to engage students during the academic year. For instance: (i) a teacher mentored a 12-member student team, a third of them girls, for a project-oriented educational robotics contest; (ii) two high-school teachers launched a robotics club with 17 boys and 23 girls who worked with various robotics kits; and (iii) another high school teacher worked with 42 boys and 39 girls on robotics. She

received 12 additional robotics kits from her school's support, allowing her students to learn and explore how to physically build robots, code, and control the robot motion. Students were also given opportunities to prototype and pitch their ideas in a technology business idea competition.

Technology business idea competition

At the end of each academic year, a technology-based business idea competition was organized whose purpose was to encourage students to explore real-world challenges in their communities, develop novel solutions for them, and present their innovations. All teachers who participated in summer workshops were challenged to mentor a team of students from their schools to partake in this activity and present their ideas in front of their peers and a panel of judges. Specifically, students were encouraged to seek out, from their home, neighborhood, school, or other familiar environments, a problem that could possibly be solved by employing mechatronics or robotics concepts. Developing and honing students' entrepreneurial skills was an important aspect of this effort, thus they were required to analyze and illustrate the market potential of their solution. Several illustrative mechatronics and robotics design submissions are reviewed in [Illustrative examples of student projects](#) subsection.

Description of the competition

Under the PBL framework, the competition was designed thoughtfully such that it integrates applications of various project elements including mechatronics, robotics, and entrepreneurship concepts in alignment with STEM learning and engineering design. Students used the robotics kits that were provided to their teachers for classroom use and provision of additional material for the prototype was limited to under \$20. Each team was represented by three to five members and the prize for the competition was in the form of a paid internship at a local startup business. Students prepared for the competition by participating in the following steps.

Identifying a problem: The competing teams identified problems in their home, school, or community environment that were deemed solvable by using an innovative technology product (specifically mechatronics or robots in this case). They conducted surveys to identify potential opportunities and their possible impact for the targeted environment. The survey constituted an important element for the competition, thus the students were encouraged to be diligent about it. Next, they formulated problem statements, brainstormed potential solution strategies, and selected one they deemed the best. Students were advised that the solutions can be in the form of an enhancement to an existing device, an incorporation of different technologies, or be entirely novel.

Designing and building: After identifying the problem and potential solution, teams designed and prototyped mechatronics or robotics devices. At this stage, they built, programmed, and tested the device ahead of the competition. Their mechatronics devices and robots were required to be mechanically stable and serve practical needs in real-world settings. The teams submitted videos demonstrating the performance of their prototypes. See [Fig. 2](#) for several robot designs entered in the competition.

Marketing: As a final step, teams were required to create marketing strategies for the designed prototype by employing concepts such as identifying consumer base, setting a product price, steps to market their product, advertising their product, budget, resources, etc. After conducting a thorough research on these aspects, the teams created a product pitch to persuade people to buy their product. They also gave their product a name, which was also their team's name and a part of their marketing pitch. Students shared all the relevant details in the form of a presentation and a reflective written assignment at the competition.

Fig. 2 Examples of student projects (A) TrackrBot, (B) Clara-BOT, and (C) RoBoiz.

Internship: Each year, one student from each of the two winning teams was awarded the opportunity to participate in a two-week, paid, hands-on, summer internship at a local company that supports young entrepreneurs. The winning teams and their teachers were free to nominate the internship recipients. This activity was incorporated to provide an intimate familiarity with technology startup industry to students so that they could experience and contribute to a company founded on the integration of entrepreneurship and technology. The project team expected this to be an effective contributor in shaping students' early experiences for gauging and developing engagement in technology startups.

Project results

Over the 3-year period of this effort, the summer workshop was attended by 30 teachers. The "self-identified" demographic information for teacher participants is summarized in [Table 1](#).

Evaluation procedure

The project evaluation was conducted by an external evaluator through the following activities.

- A survey was administered to the teachers to anonymously obtain responses and analyze data pertaining to their level of familiarity with the topics of mechatronics and entrepreneurship. The survey contained 35-items to assess teachers' familiarity with mechatronics skills, concepts, and devices introduced during the workshop. The survey also included seven items on familiarity with areas of business, intellectual property, and innovations. In addition to the familiarity surveys conducted by the external evaluator, the project team administered a technical quiz to assess teachers' math/science concepts and their understanding of engineering fundamentals *vis-à-vis* mechatronics. While the familiarity surveys were administered through an online mechanism, the technical quiz was conducted in a paper-pencil format. All pre-tests were conducted on the first day of the two-week hands-on training while all post-tests were conducted after the completion of the four-week collaborative research phase. This allowed the project team to assess any post-project improvements by comparing the pre-/post-tests. Note that teachers responded to all pre-/post-tests using self-selected unique three digit codes, which allowed anonymous data collection while permitting comparisons for pre-/post-tests for individual respondents.
- A survey was administered and analyzed concerning teachers' approaches in the educational process and their experiences during the program. To consider teachers' interests and concerns, they were prompted to indicate the level of priority for several areas in their teaching.
- Teachers were interviewed individually or in small groups and their research sites were visited to assess the authentic nature of their experiences. In the interviews, teachers detailed their accomplishments, experiences, and plans for future adoption of their learning for classroom. Visits to the research labs allowed the evaluator to observe teachers practicing what they had described during the interviews. Additional conversations with the project team members were also conducted.

Evaluation outcomes and observations

Substantial increases in teachers' familiarity with mechatronics skills and concepts and entrepreneurship topics were noted. Interview and lab visit data showcased teachers' enthusiasm in taking their learnings to classrooms for implementation. Further details are discussed below.

Mechatronics skills and concepts: While at the start of each summer workshop, teachers reported moderate levels of familiarity with the mechatronics topics, by the conclusion of each summer workshop, they reported higher levels of familiarity with the mechatronics topics. A 35-item survey assessed teachers' understanding of mechatronics concepts and over the 3 years of project implementation, teachers' self-perception improved from an average of 1.58/4.0 (pre-workshop) to 2.91/4.0 (post-workshop). The data broken down by each year of the project is reported in [Table 2](#) below.

Table 1 Demographic information of the participating teachers.

Year	Total	Gender		Race			
		Male	Female	White/Caucasian	African American	Asian	Others
Y1	9	6	3	4	4	0	1
Y2	11	4	7	5	3	3	0
Y3	10	6	4	6	0	3	1
Total	30	16	14	15	7	6	2

Table 2 Teacher's level for familiarity with the mechatronics topics.

	<i>Average of pre-test on teachers' self-perception of familiarity with project topics for mechatronics (4-point scale)</i>	<i>Average of post-test on teachers' self-perception of familiarity with project topics for mechatronics (4-point scale)</i>
Year 1	1.82	2.97
Year 2	1.25	2.72
Year 3	1.73	3.07

Table 3 Teacher's level for familiarity with the entrepreneurship topics.

	<i>Average of pre-test on teachers' self-perception of familiarity with project topics for entrepreneurship (4-point scale)</i>	<i>Average of post-test on teachers' self-perception of familiarity with project topics for entrepreneurship (4-point scale)</i>
Year 1	2.08	3.06
Year 2	1.25	3.05
Year 3	2.11	3.11

Entrepreneurship concepts: While at the start of each summer workshop, teachers reported moderate levels of familiarity with the entrepreneurship-based topics of the project, by the conclusion of each summer workshop, they reported higher levels of familiarity with the entrepreneurship topics. A seven-item survey assessed teachers' understanding of entrepreneurship concepts and over the 3 years of project implementation, teachers' self-perception improved from an average of 1.79/4.0 (pre-workshop) to 3.07/4.0 (post-workshop). The data broken down by each year of the project is reported in [Table 3](#) below.

Technical quizzes: Teacher's understanding of scientific, mathematical, and engineering foundations of mechatronics concepts improved based on the analysis of pre-/post-technical quizzes. The average of their scores over 3 years was: 45.90% (pre-workshop) and 59.65% (post-workshop); yielding 29.97% improvement.

- In Year 1, pre-to post-test scores changed from 49% to 64%, yielding an improvement of 30.6%. The analysis of a paired *t*-test on the quiz results produced a *t* value of 3.702 with a *p* value of 0.006. This outcome indicates that the null hypothesis can be rejected and the improvements in the quiz results are statistically significant at a level higher than 99%.
- In Year 2, pre-to post-test scores changed from 47.2% to 58.5%, yielding an improvement of 23.9%. The analysis of a paired *t*-test on the quiz results produced a *t* value of 3.38 with a *p* value of 0.007. This outcome indicates that the null hypothesis can be rejected and the improvements in the quiz results are statistically significant at a level higher than 99%.
- In Year 3, pre-to post-test scores changed from 41.67% to 57%, yielding an improvement of 36.8%. The analysis of a paired *t*-test on the quiz results produced a *t* value of 1.99 with a *p* value of 0.005. This outcome indicates that the null hypothesis can be rejected and the improvements in the quiz results are statistically significant at a level higher than 99%.

Approaches in educational processes: Results of the surveys indicated that teachers prioritized for their students: learning fundamentals; engaging in problem solving abilities; performing team work; honing communication skills; gaining business-related skills; practicing research skills; familiarizing with STEM-related careers; and staying abreast with technological innovation. While these are not areas in which significant pre/post changes were anticipated, Year 1 found that an increase from pre-to post-workshop survey results from an average of (3.81/5) to (4.46/5) yielding an increase of 0.65.

Interviews and lab visits: The evaluator noted that the teachers were enthusiastic in answering the questions and explaining what they had learned. During the collaborative research work, teachers explained their research topics and demonstrated what their mechatronics or robot designs were able to accomplish and described painstaking efforts in analyzing motion, fabricating devices, developing computer instructions, and testing electronic interfaces. A teacher emphasized on the importance of creating personalized assessment goals for students to support their learning progression and surfacing of misconceptions. Several teachers also shared that improvement in coding and programming capabilities is crucial for success in their classrooms. Based on their experiences with the professional development program, the teachers communicated the importance of real-world experiences in making learning relevant to classrooms, tailoring material to the context of their students, and employing experiences with entrepreneurship to make learning more meaningful. In discussing the take-away, teachers commented on their own learning experiences, particular technologies they plan to use (programming, soldering, 3D printing), and concrete projects. They also appreciated the opportunity of ongoing learning.

Illustrative examples of student projects

The competing student teams developed a variety of robotics and mechatronics-based solutions for problems in their environment. Several examples are highlighted below.

TrackrBot: Based on the surveys for their whole school and specifically the students in school's sport programs, this student team identified that athletes cannot keep pace with training and track their progress. To address this challenge, the students suggested a solution in the form of a robot that keeps a programmed pace profile for runners who are moving around the track and updates their progress on a smart-phone app. They created a mobile robot whose time, pace, and distance parameters can be specified based on the training profile for specific athletes such that when a runner finds the robot go past them, they would know to run faster. The robot was also integrated with a camera to record the runner's form. During the robot development process, students gained deeper understanding of STEM topics such as distance, speed, average, algorithm development through coding, and the functionality of various components used in the robot design, among others. Apart from the excellent prototype design, the team also provided a convincing presentation, an engaging video demonstration, a compelling business case, and well-considered marketing strategies to promote their product.

Clara-BOT: Based on the interviews of their peers, this team recognized a need to improve their school cafeteria that often gets littered around. A solution was to build a robot to pick up trash while also being educational and entertaining. The team created a robust engineering design of their Clara-BOT and endowed it with WiFi networking to communicate with other robots and facial recognition technology for school security application. In addition to a collaborative effort on their presentation and business pitch, the team showcased the robot as an environmentally-friendly solution for similar challenges in the future.

RoBoiz: This team sought to solve the problem of bottles and cans that litter the school floor by adopting the design thinking process to create their RoBoiz prototype. They considered the stages of "empathize" to identify the challenges in their school, "define" to formulate a problem statement, "ideate" to come up with potential solutions and robot designs, "prototype" to build their robot, and "test" to examine their robot design. Through this project, the students not only encouraged a cleaner environment but also promoted recycling. Their solution employed a wide range of STEM and entrepreneurship concepts such as waste collection and management, recycling, coding, environmental protection, marketing pitches, market research, user research, etc.

Similarly, by conducting surveys of their school peers or interviewing their classmates, many other teams identified challenges for entrepreneurial explorations under the umbrella of mechatronics and robotics technologies. For example, one student team opted to devise a "Silent Classroom" as a solution for distraction in learning due to disruptive noise or behavior inside or outside the classroom. The team proposed to use Bluetooth headphones integrated with a sensory system that can enable students to hear only their teacher's instruction by pressing a button on the sensory device. When students engage in group work, they have the option to hear their peers in close proximity by pressing another button on the sensory device. Apart from gaining a deep understanding of STEM concepts related to sound, engineering design, and coding, students also employed concepts of entrepreneurship by developing marketing strategies and a pitch video, all to emphasize the need of this solution and how it can help students, teachers, and schools. The "Anima" team identified the problem of lack of access to feminine hygiene products and the undue disruption and embarrassment that result when one goes about to obtain them. The team created a smart-phone app and a vending machine to facilitate the ease of availability of the product. The students can order the product using their student account through the app. Next, at the vending machine, students perform required touchpad interaction and present their ID for user identification and validation, following which the vending machine dispenses the items using the motors. In developing this prototype, the students utilized STEM concepts of coding to develop the app, and capacitors and touch sensors for the vending machine. Moreover, they also took a stance toward social justice by brainstorming a solution for a poignant problem such as lack of access to hygiene products for female students. The team also built a strong business case around the problem and suggested that such a solution can be adopted beyond schools in workplaces and public spaces that have women employees or visitors.

In written reflections about their project experiences, team members indicated that participation in this activity allowed them to learn how to address myriad social, organizational, and technical challenges. For example, students indicated that they learned teamwork strategies, including communication, brainstorming, and patience, to effectively plan, organize, schedule, and manage their time and activities. Moreover, they learned about robotics engineering and programming, 3D printing, hardware and software debugging, creating and editing videos, app development, etc.

Discussion

Based on the outcomes and observations of the research and evaluation of the program, an evident improvement in outcomes of teachers' self-perception of familiarity with mechatronics and entrepreneurship concepts was noticed. A growth in their understanding and use of technical and scientific terms was noted as teachers used new vocabulary terms related to programming, methods of measurement, etc., during the external evaluator's visit to their research lab sites and on the technical quiz. As they worked with industry professionals and researchers, teachers developed their work habits and mentioned the importance of planning step-by-step to understand about the underlying connections of novel concepts. Teachers were enthusiastic about the real-world aspect of project integration in their classrooms and received opportunities of understanding of scientific, mathematical,

and engineering foundations of mechatronics concepts. The emerging themes showcased a shift in leading teachers to “doing science” as opposed to reading about it. They highlighted that the integration of entrepreneurship can add a pragmatic dimension that would motivate their students. For instance, they explored 3D printers not just to fabricate simple items but to use them in conjunction with science-learning areas and contextualizing to introduce newer methods to students. They appreciated the ongoing learning opportunity provided to them via this professional development program and believed that they must themselves be engaged in learning. Some teacher testimonials are shared below.

- “Knowing more about business and industry will make abstract concepts more relevant to students by placing them in a context and showing how they may be impacted.”
- “The students are always buying the latest innovative devices. And they always ask teachers about how these devices function. It is wise for teachers to have a basic idea about the industry.”
- “By tying the math I teach to industry, students will see more of the real-world connections and find it more meaningful/purposeful to study.”
- “If I am able to determine the trend in any given industry, I will be able to guide my students more in what they should pursue for college and what skills to develop to help them become successful once they join the workforce.”

The teachers also appreciated the annual technology business idea competition as it provided an additional opportunity for students to apply what they had learned and present it to a larger group of audience. For instance, the teachers reflected as below.

- “Being able to watch them think deeply about an issue and work together to come up with a solution, is exactly what education should teach them. I tried to take a very hands-off approach to my students’ involvement in the competition, because I wanted to see what they could accomplish all on their own, and I have been fairly impressed considering that we don’t have a program or course of study or even a team dedicated to robotics and coding.”
- “As a result of our work together students demonstrate curiosity, stamina, the ability to rethink decisions and reiterate models. They engaged in the engineering design process and were readily able to work with a variety of classmates on varying assignments. They used their specific talents and gifts to help come up with solutions and solve problems.”

The graduate researchers’ school visits assisted teachers in organizing robotics activities and teams and enabled students interested in robotics to consult with researchers about expectations, commitments, and technical aspects to be successful in such activities. Collectively, these educators impacted over 500 students, with approximately 50% being women and a large proportion from groups underrepresented in STEM disciplines. These teachers acted as mentors to the robotics clubs and they developed and implemented lessons and activities based on the guided-training curriculum of the program. They used the mechatronics kits provided through the project and procured additional kits through their schools. The activities of student clubs were organized once or twice every week. The students actively worked on designing, programming, and testing robots. Through lessons, robotics clubs, and annual competitions, students explored multiple opportunities to design solutions for problems in their schools and communities, in turn developing knowledge and skills for STEM learning, engineering design, and entrepreneurship, all leading to greater engagement and interest in STEM pathways. Winners of the annual competitions were awarded internships following which one student reflected that the activities enabled her to improve research, reading, and writing skills and that she felt confident in finding relevant information and prioritizing important tasks a lot faster. Another student reflected about his experience of creating new opportunities for himself and following his dreams, even when they may not seem realistic. To summarize, over 3 years the project provided numerous, hands-on learning opportunities for teachers and students to become familiar with and experience mechatronics, robotics, and entrepreneurship concepts situated in real-life problems. The positive outcomes indicate that participants increased their knowledge, interest, and achievement in these concepts, with a potential of continued deployment in classrooms for the future.

Conclusion

This chapter discusses the design, implementation, and evaluation results of 3 years of a summer professional development program that focused on familiarizing teachers with mechatronics, robotics, and entrepreneurship concepts to facilitate meaningful and engaging STEM learning. During a six-week period, teachers immersed in hands-on learning, collaborative research, and industry-based experiences. Teachers also participated in a three-day lesson development workshop that focused on the design of NGSS-plus-5E lessons and their practice enactment with peers. The evaluation data showed an improvement in teachers’ familiarity with mechatronics, robotics, and entrepreneurship concepts, and an increased enthusiasm in implementing the real-world lessons in classrooms. Overall, 30 teachers received the guided training, research experiences, and industry exposure. Collectively, these educators impacted over 500 students, vast majority of who come from weaker socio-economic backgrounds, with approximately 50% being women and a large proportion from groups underrepresented in STEM disciplines. The teachers appreciated the project and continued to use the mechatronics and robotics kits provided to them beyond the program and appended the kits using resources from their own schools. The activities were organized 1–2 times a week after school hours and engaged the students in designing, programming, and testing robots and learning the various related STEM concepts.

Appendix: A

Table A.I NGSS-plus-5E lesson plan on alternative energy using windmills.

Lesson description: In this lesson students will utilize their engineering skills to create a working windmill. They will have opportunities to redesign their windmill to increase its energy output and share detailed information about how the windmill functions. After working with the windmill, students will be tasked with researching a specific form of alternative energy and present their findings to their peers.

Learning outcomes: Students will be able to:

- Explore the process of engineering design by creating a scaled model of a windmill and evaluate its energy output.
- Identify human impact on the environment by analyzing various data sources, including satellite imaging data.

Prior student knowledge:

- The concept of alternative forms and sources of energy
- Consequences of human impact on natural systems, e.g., deforestation, fossil fuel consumption, overpopulation, pollution, etc.
- Operation of a multimeter and other varied electrical components and equipment

Possible preconceptions/misconceptions:

- Electricity comes from the wall socket where you plug in and it is created (no conservation of energy)
- Alternative forms and sources of energy are not readily available for everyday use
- Wind turbines are not very large
- If it is not windy (wind power) or sunny (solar power) there will be no electricity available for those reliant on alternative energy sources

Performance expectation(s): HS-ESS3-4. Evaluate or refine a technological solution that reduces impacts of human activities on natural systems.

Science and engineering practices

Constructing explanations and

ESS3.C: Human impacts

on earth systems

ETS1.B: Developing

possible solutions

Crosscutting concepts

Stability and change

Influence of science, engineering, and technology on society and the natural world

5E lesson plan:

Engage: Discuss in groups: What is the story behind turning on your light bulb? How many people does it take to turn on a light bulb?

Explore: Groups will prototype and design a scaled model of a windmill based on a scenario where the city mayor wants to use a new energy source using a turbine tower, motor, dowels, hub, multimeter, etc. This is to be done under a given budget to build a cost-effective turbine. Students will present their designs and run trials. Later, they will reflect on the following questions and upgrade their design.

- What was the dependent variable in this experiment? (e.g., voltage, energy produced, etc.)
- What were the variables you were manipulating? (e.g., type and amount of material, angle and surface area of blades, number of dowels, etc.)
- What design elements seemed to work best? What failed? Why do you think this occurred?

Explain: Understanding the windmill: parts (blades, low speed shaft, high speed shaft, anemometer, wind vane, controller, generator, yaw drive, brake) Questions: Why are the blades curved? What are some applications of windmills? What are some limitations of windmills? Which features are important for windmill design?

Elaborate: Research an alternative energy that is currently being used somewhere in the world and prepare a brief presentation. Explain how it compares to our traditional energy (burning of fossil fuels).

Evaluate: Present multiple iterations of the design and observations during each iteration. Explain the reason behind the changes in design. Submit reflections.

Table A.II NGSS-plus-5E lesson plan on bridges and forces.

Lesson description: In this lesson students will design scaled prototypes of different types of bridges and instrument them with force sensors. Students will analyze the effect of strategic placement of various force sensors, near the gusset plates of truss, on the structural integrity and stability of the bridge. As the students construct the prototype and instrument it, they will explore strategies to effectively monitor the amount of load forces in critical locations of the bridge.

Learning outcomes: Students will be able to:

- Explore and examine the causes of historical bridge collapses in the US.
- Calculate forces of compression and tension in their scaled prototype of a bridge.

Prior student knowledge:

- Concept of compressive and tensile forces on a bridge
- Knowledge of different types of bridges and historical bridge collapses in the US
- Familiarity with Arduino microcontroller interfacing and coding

Possible preconceptions/misconceptions:

- Only certain types of bridges can collapse
- It is difficult to determine forces acting on a bridge

Performance expectation(s): MS-ETS1-2. Evaluate competing design solutions using a systematic process to determine how well they meet the criteria and constraints of the problem.

(Continued)

Table A.11 NGSS-plus-5E lesson plan on bridges and forces.—cont'd

Science & engineering practices	Disciplinary core ideas	Crosscutting concepts
Engaging in argument from evidence	ETS1.B: Developing possible solutions	Influence of science, engineering, and technology on society and the natural world
5E lesson plan:		
Engage: Discuss in groups: (i) How do the forces of tension and compression affect a bridge? (ii) How do gravity and externally applied load, e.g., a truck carrying goods, affect a bridge?		
Explore: Using art supplies, students in small groups design scaled prototypes of different kinds of bridges, e.g., arch bridge, simple beam bridge, cantilever bridge, cable stayed bridge, suspension bridge, and truss bridge. Students calculate and quantify the force and resistance on the bridge and discuss solutions to design a better bridge. Based on their knowledge of compressive and tensile forces, they determine the location of force sensors (e.g., on street level above the gusset plate). Using the console of an Arduino microcontroller interfaced to the force sensors, students record the force sensor measurements corresponding to the placement of toy cars and trucks at different locations of their bridge prototype and use these measurements to calculate forces experienced by key elements of the bridge.		
Explain: Demonstrate an understanding of relevant vocabulary terms: tension, compression, buckling, load, live load, etc. Analyze graphs for different gusset plates and show an understanding of dependent and independent variables. Plot a graph of the demand to capacity ratio as a measure of bridge safety.		
Elaborate: Compare and contrast pros and cons of different kinds of bridges (simple beam bridges tend to sag in the middle, truss bridges can be strengthened by the assembly of interconnected triangles, etc.).		
Evaluate: Students will assume the role of an officer or a scientist, who evaluates the process of design and construction of new bridges, for the Federal Highway Administration or the National Transportation Safety Board. They will hypothesize about various sensors that can be used for condition monitoring of a bridge structure. Through an essay and a presentation, they will respond to the following prompts: Which kind of bridge has greater stiffness and why? Which type of bridge needs more support under the bridge deck and why? Can you comment on the tensile and compressive forces, including if they are same, for a: moveable, lift, bascule, or swing bridge? What is the bridge safety in terms of capacity ratio?		

Acknowledgments

This work is supported in part by the National Science Foundation grant RET Site EEC: 1542286. The authors thank the 30 teachers for their participation in this study. The authors also thank Dr. Sai Prasanth Krishnamoorthy, a doctoral student during this study, for his significant educational, instructional, mentoring, and research contributions to this effort. Moreover, the authors thank the following for their invaluable support: (i) the faculty mentors of teachers; (ii) graduate student collaborators of teachers; (iii) NYU Tandon School of Engineering's Center for K-12 STEM Education and Incubators Initiatives; (iv) NYU Entrepreneurial Institute; (v) industry partners; and (vi) external evaluator.

Dual challenge for computational thinking to address

Today's youth will live and work in a world that is heavily influenced by computing principles (Barr and Stephenson, 2011) and by the misleading data artifacts integrated in current computing that maintain and perpetuate social inequalities (Bradford, 2017; Robinson, 2019). This dual challenge is one that, in today's classrooms, educators are largely not being prepared to address in their teaching and therefore, students are largely not being prepared to encounter (Kessler, 2007; Fraillon et al., 2014). In this paper, we present computer science (CS) teacher preparation and orientation approaches, the role of social justice within computational thinking (CT) and CS spaces, an introduction to a CT for Equity Framework and an introduction to how one teacher education program at the University of California, Los Angeles (UCLA) is preparing educators to use CT to address this dual challenge.

CT is quickly becoming a prerequisite skill for most endeavors of the 21st century (Wing, 2008). In the last 20 years, nearly every field related to science and mathematics has seen the growth of CT, and sense-making around data is demanded of engaged community members (Buitrago Flórez et al., 2017; Utts, 2015). This shifting landscape requires that science and mathematics education shift toward CT, which in turn necessitates that teacher preparation programs respond by redesigning curriculum, clinical experiences, and mentor development. Computational thinking refers to the thought processes involved in expressing solutions in a way that can be carried out by a computer (Cuny et al., 2010; Aho, 2011; Lee, 2016), with the distinction that CT additionally describes many problem-solving skills involved in CS (CS for CA, 2021). CS is "the study of computers and algorithmic processes, including their principles, their hardware and software designs, their [implementation], and their impact on society" (Tucker et al., 2003, p. 6). The K-12 CS Framework places CT at the core of CS, with CT comprising four of its six practices and stating that "the most effective context and approach for developing computational thinking is learning computer science; they are intrinsically connected" (K-12 Computer Science Framework, 2016, p. 69).

Thanks to the "CS for All" movement, great effort has been put forth to promote CS education. While this effort occurs at the national-level, we situate our response in the context of the state of California. To increase the number of highly qualified CS teachers, California developed an alternative CS authorization route for teachers in 2019 that requires secondary teacher candidates to complete coursework in five domains of computing content. This coursework is common to (a) the introductory CS undergraduate programs and (b) the high school Advanced Placement course that introduces students to the foundational CS concepts of the field and the impact of computing on society. Many of the current secondary level CS supplementary authorization preparation programs across California are offered through a CS department, often in collaboration with the teacher education program faculty and staff, and offer coursework heavily situated within the domain of CS.

These programs are typically designed to fulfill both the credentialing requirements set forth by the California Teacher Credentialing Commission and expose teachers to introductory computing principles and practices typical for high school computing courses such as Exploring Computer Science or Advanced Placement Computer Principles. At present, mathematics teachers within California are permitted to teach CS courses regardless of their CS experience. California's CS Secondary Authorization increases content preparedness for math teachers and broadens the opportunity for other disciplines to provide CS instruction within their school sites. Historically, a) CS educator recruitment approaches provided in-service teachers professional development and curricular support that range from a few days to several weeks (Liu et al., 2011) or b) involved recruiting CS professionals to the classroom. States and local districts continue to innovate approaches to address the lack of CS teachers in secondary spaces. However, equity and social justice issues are rarely the central organizing theme for science, technology, engineering, and mathematics (STEM) teacher education programs and largely absent from CT/CS coursework (Mills and Ballantyne, 2016).

The foundational argument of this paper is that secondary CS courses and teacher preparation for CS courses are fundamentally inadequate to address the dual challenge of preparing students to use computing principles, and to do so in ways that apply a critical framework around societal inequities. We advance a framework of preparing educators to utilize CT to address these challenges. In the sections that follow, we first explain the structure of the program designed at UCLA by outlining our response to a set of barriers educators face in preparing students to critically use computing principles. This is followed by a brief set of examples of the pedagogical practices that teacher candidates have developed through their participation in UCLA's program. We contribute an approach to preparing and empowering social justice educators to support students understanding and using CT in their work and their lives.

The STEM + C3 urban teacher residency program

UCLA's Teacher Education Program (TEP) has responded to the need for more critical computing education through the development of an urban teacher residency program called STEM + C3. The three Cs referenced in the program name represent a Community of Practice, Computational Thinking, and Computer Science secondary authorization. This program aligns a humanizing teacher education program (Bartolome, 1994; del Carmen Salazar, 2013) with K-12 academic achievement standards and state and national content standards. STEM + C3 prepares approximately 16 new secondary mathematics and secondary science teachers each year and situates pre-service teachers' learning from university coursework in the context of mentors' classrooms in small autonomous schools within urban communities. Teacher candidates begin their student teaching experience on the first day of school and continue with the same mentor teacher and classes through the entire school year.

The residency program employs a gradual release of responsibility model (Fisher and Frey, 2013), where pre-service teachers observe during the first few months of their student teaching, co-plan, and co-teach during the next few months, and eventually take responsibility for two of their mentor's teaching periods for the remaining months of the school year. After one year of coursework and student teaching, pre-service teacher candidates obtain their preliminary teaching credential in a single subject as well as secondary authorization in CS, and begin their teaching career as full-time teachers of record. During the second year of the STEM + C3 program, teachers continue coursework toward the completion of a master's in education degree, as well as participate in a Community of Practice to support CT integration into their curriculum.

Preparing teachers with CT pedagogy

The design of UCLA's STEM + C3 program responds to several specific barriers educators face in developing pedagogical practices to teach CT and prepare students for lives in a world steeped in data and computing. Below, we explain three of those barriers followed by STEM + C3's response.

First, there are not enough well-trained teachers to meet the needs of schools. California created its own K-12 Computer Science Strategic Implementation plan, but currently faces a critical shortage of CS teachers (Sutcher et al., 2016) as schools struggle to respond to the increasing demand for CS courses in high school. In the year 2019–2020, 43 states reported teacher shortage in science and 47 in mathematics (including DC and Puerto Rico) (U.S. Department of Education Office of Postsecondary Education, 2000). The training for pre-service teachers is inadequate to fulfill this demand because the licensure pathways in many states do not require credentialed candidates to engage in CS coursework, learn CS pedagogies, or complete fieldwork in CS classrooms. As a result, there is a vacuum of quality CS teachers providing CS education for K-12 students, particularly students in high-need schools, which are far too often staffed by novice teachers (Borman and Dowling, 2008). In response, the STEM + C3 program is designed to train qualified STEM educators, 80% of whom are first generation educators of color who majored in STEM fields, and ensure retention of these teachers. All pre-service teacher candidates enroll in and complete four additional courses focused on computational thinking, programming in R, software design, and the design of the internet. This coursework preparation allows pre-service teacher candidates to apply for a supplementary secondary authorization in computer science.

Second, a focus on increasing the quantity of teachers qualified to teach a CS course is inadequate to ensure that all students learn about CT or computing principles. The Kapor Center reported that 42% of public high schools in CA offer at least one CS course, and provide enrollment access to approximately only 5% of high school students (Koshy et al., 2021). The report also stated that despite the \$65 million increase in CS funding, access to computing through stand-alone CS courses are not fulfilling a vision of "CS for All". In response, there has recently been a rally to integrate CT into core STEM courses and standards, in contrast to only having CT taught in a CS course. The goal of engaging in CT through core content areas is to increase student access and participation to CT and CS concepts and broaden both teacher and student perspectives around what CS can look and feel like (Weintrop et al., 2015). The meaningful use of CT opportunities in STEM curricula can deepen learning of mathematics and science concepts and reflect the many ways STEM professions are practiced (National Research Council, 2011; Sen-gupta et al., 2013).

The integration of CT into classroom standards is an important and necessary step to increasing student access and exposure to computing practices. The practice of "using mathematics and computational thinking" in Next Generation Science Standards (NGSS) reflects the growing importance of computation and digital technologies across the scientific disciplines (NGSS Lead States, 2013). The Common Core framework in mathematics also states that students should be able to use technological tools to deepen

their conceptual understanding ([National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010](#)). In addition, recent innovations in CS education such as Exploring Computer Science (ECS), Introduction to Data Science (IDS), and AP Computer Science Principles (APCSP) highlight the importance of inquiry and equity-based practices to broaden access and participation in computing. Typical high school CS curriculum exposes students to a range of computing concepts that use a programming language to construct coherence across topics. CT provides teachers an approach to connect across concepts in CS and other disciplines.

While expectations for teachers to use CT in math and science coursework are clear, the inclusion of these practices into standards, in and of itself, offers little guidance for teachers who will be required to realize them in their classrooms. As has been learned from teachers' efforts to enact other Science and Engineering Practices (SEPs) in the NGSS, ([Reiser, 2013](#)) teachers must be empowered with pedagogical practices and purposes to integrate CT in their classrooms. The STEM + C3 program trains teachers to integrate CT concepts into existing math and science teacher repertoires, especially in lower-level math and science courses, by helping to identify the overlap and the differences in CT practices with math or science practices. This is necessary because CT practices often overlap heavily with the practices of math and science, blurring the distinction between students' use of CT and students' disciplinary practices. Identifying the difference is necessary so teachers can meaningfully separate the practices and make those distinctions explicit to students. For example, in STEM + C3, teacher candidates explore Appendix F of the SEPs in the NGSS that states "Computers and digital tools can enhance the power of mathematics by automating calculations, approximating solutions to problems that cannot be calculated precisely, and analyzing large data sets available to identify meaningful patterns" ([National Research Council, 2013](#), p. 10).

Teachers new to CT often consider any use of technology as a CT practice or over-generalize CT as a simple problem-solving approach. For example, the steps to solve a mathematical problem algorithmically on paper versus writing an algorithm to solve the same problem are interrelated yet distinct tasks. In STEM + C3, teachers discover that examining and framing the NGSS's SEPs and the Common Core's Standards for Mathematical Practices with and without CT creates multiple opportunities to approach content from different perspectives and highlight distinctions between the disciplines. Identifying the overlap and unique distinctions are also necessary so teachers can engage in CT practices within typical math and science classroom contexts rather than within CS classrooms. STEM + C3 helps teachers see CT in computer-free tasks that are common in math or science classrooms, and further helps teachers identify and create "unplugged" CT opportunities ([Sim et al., 2021](#)).

Third, a focus on data and data tasks are absent in high school classrooms relative to the prevalence of data and data tasks in real-world contexts. The International Data Science Schools Project published a framework building a case for data science as a stand-alone course pathway that would ensure "sufficient understanding and appreciation of how data can be acquired and used to make decisions so that students can make informed judgments in their daily lives" ([IDSSP Curriculum Team, 2019](#), p. 7). Alternative mathematical pathways are an important part of increasing student CT and data literacy within STEM spaces. While there are notable examples fusing data, technology, and computing into lessons and courses (e.g., IDS, Concord Consortium Common Online Data Analysis Platform, Bootstrap, YouCubed), most students do not have access to such experiences. STEM + C3 responds by closely tying CT to data-related tasks, such as the data cycle or the statistical investigation cycle ([Bargagliotti et al., 2020](#)), with the goal of preparing students to "work with data and be critical consumers" ([Gould, 2021](#), p. S16).

Preparing teachers with CT for equity pedagogy

The design of UCLA's STEM + C3 program responds to additional barriers educators face in developing pedagogical practices that disrupt educational and social inequalities. Below, we explain two of those barriers followed by STEM + C3's response. We conclude this section by sharing the seven CT for Equity practices pre-service teacher candidates are taught in the STEM + C3 program.

First, CT/CS teacher education often fails to consider the diverse needs and contexts of schools and students which results in a lack of support in developing equity-oriented pedagogy. In a recent survey conducted by the Kapor Center and the Computer Science Teachers Association, 39% of CS teachers reported that did not see the importance of covering computing's role in perpetuating biases related to racism, sexism, and other social justice issues in the classroom ([Koshy et al., 2021](#)). A lack of curricular connection to students' lives has implications for student participation and outcomes, because students are more engaged with CS when it is presented alongside social justice issues ([Ryoo et al., 2019, 2020, 2021](#)). [Gordon and Heck \(2019\)](#) found that of CS teachers surveyed, "Fewer than one-quarter feel very well prepared to differentiate computer science instruction to meet the needs of diverse learners or to incorporate students cultural backgrounds into computer science instruction (p. 9)." The CS for Equity teaching practices and pedagogies support the integrations of student's lived experience and culture as an asset that also provides a differentiated pathway for students. The STEM + C3 program explicitly focuses on educational equity and justice, and provides pre-service teachers the opportunity to situate relevant social justice topics into curriculum, and use CT practices to open opportunities to explore issues of social justice within the classroom. This approach, called "CT for Equity", seeks to empower teachers to use CT in ways that explore, express, critique, and create artifacts about the world around them. It extends beyond the skills and meta-cognitive processes necessary for engaging in CT or computing tasks, and reaches toward classroom environments and curricula that affirm a student's rightful presence within the STEM classroom and the larger STEM community ([Barton and Tan, 2019](#)). CT for Equity entrusts teachers and students to use their data analysis and computing skills to develop and critique narratives about the

world around them as they become data storytellers who go beyond content, visualizations, and interpretation; they breathe life into the analysis, emphasizing the context, ethics, and implications of the data that are important to them and to their intended audiences. In STEM + C3, CT, data, and equity are inextricably linked, and this nexus serves as the coherent thread that weaves together different facets of our program.

A second barrier highlights that simply understanding CT terms (e.g., “abstraction” or “expressing algorithms”) does not clarify the purpose or process of learning CT or explicate the place of equity in that learning. Often, teachers new to CT and CS may perceive or position the incorporation of CT or computing concepts solely for career opportunity, as a means to recruit students into the STEM fields, or to increase enrollment. While CT plays a critical role in the STEM disciplines and fields, STEM + C3 is not focused on increasing workers in the STEM pipeline, but rather on CT as a tool for empowering students to use problem-solving and design skills that are relevant to the students’ content courses, and more importantly, to their lived experience.

STEM + C3 explicitly expands the purpose of CT in several ways. A means to foster CT for empowerment is through cognitive apprenticeship. Through cognitive apprenticeship (Collins et al., 1989), teachers scaffold the content and utilize modeling and coaching practices to assist students with developing the metacognition necessary to better connect computing and data with specific problem-solving approaches, all the while supporting the student’s sense of agency (Hadad, 2020). By encouraging the externalization of the “thinking” of CT, educators can reduce the mystery of how CT/CS practices are enacted and assist students in seeing themselves as computational thinkers.

CT embedded within data-rich experiences also provides opportunities to explore issues of social justice relevant to their student population and affirm all students’ identity and culture, and empower students to become agents of change. The interactional roles between data, CS, math and science situated within CT for Equity framework are reflected in Fig. 1.

Given the lack of familiarity with CT for many teachers, especially outside the context of a CS or programming curriculum, the STEM + C3 program developed basic definitions of CT practices as the foundation of teacher learning. CT for Equity is defined by seven practices, summarized in Fig. 2, which aim to expand CS access by creating different experiences for those learning about computing within their high school classes. This framework supports teachers in integrating CT concepts into existing required high school courses to increase access to computing and digital literacy. These definitions can be applied across many disciplines, have clear connections to data-centered tasks, and reflect a situated or critical lens (Kafai, 2016; Kafai et al., 2019). CT in these definitions are tools that assert a student’s rightful presence (Barton and Tan, 2019) in the classroom and an opportunity to liberate students from traditional pedagogical paradigms that privilege uniformity.

The definitions of these CT practices, as seen in Fig. 2, became the foundation for the STEM + C3 program and were developed in a multi-step iterative process that engaged the first cohort of teacher candidates. These functional definitions of CT support the NGSS SEPs as well as the California Common Core Standard (CCCS) Standards for Mathematical Practices, and build on existing knowledge largely shaped by International Society for Technology in Education CT Teacher and Leadership Toolkits and the K-12 Computational Thinking Frameworks. The CT practices hope to reflect how teachers make connections to data in STEM classrooms, leverage CT to support concept development, and use CT as a means to collaborate and communicate around issues of importance to students (K-12 Computational Thinking Framework, 2016). Specifically, they build on Jeanette Wing’s initial descriptors of CT (Wing, 2008) and recent findings from ECS and IDS evaluation reports (Gould et al., 2016) which indicate that ECS and IDS are powerful resources to improve STEM teacher preparation and development.

Fig. 1 Computational thinking for equity framework.

Computational Thinking for Equity CT for Equity seeks to empower students to use problem-solving and design skills that are informed by computing to explore, express, critique, and create artifacts about the world around them.	
Develop and Use Abstraction Consider and focus on key components and filter out unnecessary details to make problems easier to solve and includes acknowledging the benefits and consequence of generalizations and or lost details.	Algorithmic Thinking Recognize when a solution to a problem can be broken into step-by-step instructions. This set of instructions considers the audience, the purpose, and can be used by someone else or a computer.
Decomposition Break down a problem of interest into smaller, more manageable components, and the ability to describe this process in detail in order to make decisions, obtain help or find solutions.	Debugging and Evaluating The ability to identify and correct errors within an algorithm, and ensuring your solution is effective, feasible, and considers the impacts on various identities.
Exploring Equity Issues through Computational Thinking and Data Encourage alternative ways of solving problems. Promote inclusivity and provide universal access to all students, particularly those from underserved and intersectional populations.	Collaborate Around Computing and Data Work with others to understand, develop, and design computational artifacts or data visualizations to explore and explain phenomena, solve problems, or develop solutions that matter to students.
	Communicating with and About Computing and Data Describe, explain, and justify observations, patterns, and predictions around computational artifacts and data within the context of the problem as well as communicate applicable ethical considerations.

Fig. 2 Definitions of computational thinking practices used in the "CT for Equity" framework.

Learning spaces for teacher candidates

In this section, we outline the structure of the STEM + C3 program to explain the various learning spaces in which pre-service teacher candidates participate and how those spaces afford opportunities to learn the CT for Equity practices described above. The mission of both the UCLA TEP and STEM + C3 is to prepare teachers with the commitment, capacity, and resilience to work in and with the most underserved communities, and therefore, each of the five learning spaces share a central focus on achieving educational equity and social justice.

UCLA STEM + C3 builds on the knowledge and experience gained from the successful design and implementation of UCLA's IMPACT Urban Teacher Residency Program which was created in 2009 to develop highly prepared teacher leaders through a variety of coursework (language acquisition, learning theory, social justice) and field experiences redefining teacher quality (Kawasaki et al., 2020). These commitments and experiences structured the STEM + C3 program into two general categories: three academic learning spaces and two professional development spaces, as seen in Fig. 3. Academic learning spaces include UCLA TEP courses, a sequence of four CS courses, and the residency program in mentor teachers' classroom. Professional development spaces are the Partners in Practice, focused on reciprocal learning with mentors around questions of equity in education, and the Community of Practice, focused on experiencing and designing CT and data classroom lessons and pedagogies.

Teachers in the STEM + C3 program learn about CT for Equity primarily in the professional development space of the Community of Practice and the learning space of the CS coursework. The objectives of the Community of Practice are to a) operationalize the interdisciplinary nature of science, technology, engineering, and mathematics in STEM courses, b) integrate CT and CS concepts into NGSS or CCCS courses, and c) develop a critical mass of effective teacher-leaders who can bring high quality STEM teacher learning and professional development to scale. In a series of six workshops a year, teachers engage in lessons which integrate CT into math and science spaces and then reflect upon the pedagogical purposes, intent, and framing. In the second year of the program, teachers continue to explore problems of practice that center equity, data, and CT both within their Master's research project and the Community of Practice.

In the 12-months of the CS coursework, participants complete a sequence of courses that explores CT within the context of CS concepts such as data structures, foundation of programming using R, and the role of the internet, social media, and connectivity within digital devices. In the final course, participants work collaboratively to identify a large, multivariate dataset relevant to their

Fig. 3 Organizing structure of STEM + C3 program.

classroom content and context, and then design and build a Shiny web application (a data visualization dashboard). Teachers then share their data dashboards and accompanying lesson plan with each other in a showcase. Across this learning trajectory, CS and data opportunities within STEM classrooms are connected to CT.

The coursework sequence positions CT as a coherent thread that connects a student's STEM experiences together over the course of their K-12 education journey. Not only can CT connect together discrete CS experiences such as "hour of code" tasks to a robotics course, it is also used when programming sensors in physics or programming functions for different mathematical displays in trigonometry. At the center of all of these courses lies CT. Participants learn that CS is more than just developing students' capacity to use technology; through active engagement and deeper learning participants come to understand the role of CT, problem solving, algorithmic thinking, creativity, and collaboration in the context of CCCS for math and NGSS.

How teachers connect CT, equity, and data

To illustrate the impact of the STEM + C3 program on teachers' developing professional practices, we share selected examples of how preservice teacher candidates described the practices and purposes of integrating CT in their STEM courses. These examples come from pre-service teacher candidates who participated in the first cohort of the program and are drawn from their reflective writing in various learning spaces. The three examples (with pseudonyms for teacher candidates) were selected to highlight how teachers come to develop their own orientation to CT for Equity. Each excerpt was written in response to an open-ended prompt that invited teachers to reflect on how and why they integrate CT in their courses. In describing each of the excerpts from the pre-service teacher candidates, we link the candidates' ideas to the guiding framework of the STEM + C3 program to explicate the learning that this program facilitated.

By integrating CT students develop the tools they need to be a more critical member of society. The idea is that students don't just consume information but actually get to learn how information is gathered, analyzed and presented in order to critique the information that is constantly being communicated to them. One thing I really like about CT is that data practices can be very relevant to what is occurring in the students' community/world and therefore students are able to use real world experiences as they learn. *Jasmine, 12/2020 Programming Course Final*

CT makes STEM relevant and accessible to students by scaffolding problem-solving. Students can then connect this to problems of any size or relevance to their own lives. It also promotes students' independence, autonomy, self-driven inquiry etc because CT practices are skills that students can apply to many situations. *Ophelia, 3/2022 Software Course Final*

My students have interacted with computational thinking in many ways through different projects and activities in class. For example, my students did an endocrinology lab where they had to use their knowledge about feedback loops to figure out which specific hormones were injected into rats during a research study. My students actually worked to identify specifically how they engaged with the different computational practices: decomposition, algorithm thinking, debugging, pattern recognition, abstraction. Computational thinking allowed my students to think critically about solving problems. Computational thinking allowed my students to also find purpose in what they are doing or trying to accomplish during class. *Carissa, 2/2022 Community of Practice Reflection*

There are four aspects of Jasmine, Ophelia, and Carissa's reflective writing that we examine here to illustrate how they understand the purpose of CT and CT for Equity from their participation in STEM + C3. First, all three teacher candidates described a common purpose of supporting their students in becoming critical, independent problem solvers and citizens. Supporting students in developing problem solving was a universal goal for all ten candidates in this cohort (Clark et al., 2022). Problem solving is a foundational practice for both math and science disciplines and is a familiar entry point for teachers and reflects the ways in which the Community of Practice and CS Courses in STEM + C3 are designed around problems of practice that CT can address.

Second, Jasmine, Ophelia, and Carissa all wrote about how CT supports the relevance and importance of STEM learning and classroom tasks. These participants describe how students find relevance and a sense of purpose through connections to real-world and community issues. The STEM + C3 program designed a plethora of opportunities for teacher candidates to see the value of relevant teaching and to develop practices that supports relevant pedagogy. For example, STEM + C3 CS coursework kicked off with explorations designed to engage teacher candidates in dismantling STEM stereotypes and created counter-narratives through data and CT. Whether teachers explored intersectional representations of STEM community members, described search-engine bias within images tagged as "scientist", or used R language to explore Youth Risk Behaviors data from the Centers for Disease Control, every task in the CS courses was situated within the lives and experiences of both teachers and students. To communicate the commitment of the STEM + C3 program to equity and relevance, a major component of every CS course final was for teacher candidates to describe the implications of their new CS learning, how the CS learning was supported by CT for not only themselves, but also their urban student population.

Third, Jasmine wrote explicitly about the role of data in her teaching, and data practices are central to the learning experiences of candidates in the STEM + C3 program. In fact, all ten of the candidates in this cohort described relating course concepts to data, specifically providing data (primary or secondary) to students to achieve their instructional goals, and situating the analysis and interpretation of those data as necessary to learn concepts and/or engage in a science or math practice (Clark et al., 2022). Early on within the program, participants experienced how data storytelling through the data cycle could be used to structure classroom inquiry in a way that leveraged data as a tool to develop conceptual understanding in math or science. The enactments of CT through data varied among the teachers' reflections, whether it be with an exploratory data analysis task or examining techniques used to intentionally mislead audiences with data visualizations and representations. Interactions with data offered teachers an opportunity to simultaneously integrate CT, CS, and math/science concepts together. Data were treated as an object in which CT and Equity could be explored within the classroom. This approach is reflected in the emphasis of data across the four CS course sequence.

Fourth, Carissa described helping her students identify the differences and overlap between CT practices and science practices. This is exactly the skill she and her classmates learned for themselves, and she translated this to an activity for students. The practices detailed within NGSS and CCCS for math were written to be domain specific. While it may be easy for experts to identify how these practices are applied to other disciplines, it is not obvious for students. CT for Equity practices are generalizable and thus transfer to a variety of contexts beyond STEM to other content areas, as well as daily life experiences from finance to statistics around a favorite sports team or social media influencer.

The connections and distinctions between math/science practices and CT practices were modeled in a series of think-aloud activities by CS instructors, professional development providers in Community of Practice, and by the teachers themselves in their reflections. If students are to see themselves as capable users of technology and agents of change, they must be provided ample opportunities within a variety of contexts to incorporate CT into their repertoire of problem-solving approaches. The integration of CT into a student's academic experience may also positively impact the way they see themselves and their relationship to computing, perhaps inspiring future CS course enrollment or helping to foster a positive STEM identity.

Conclusions

This paper presented the UCLA STEM + C3 program's approach to teacher education which aims to prepare youth to live and work in a world that is heavily influenced by computing principles, and which highlights misleading data artifacts that maintain and perpetuate social inequalities. The guiding framework of the program is a set of seven CT for Equity practices that expand the notion of CT beyond problem solving assisted by a computer or other technology to include issues of educational and social equity and justice. The STEM + C3 program represents a major advancement in meaningfully preparing teachers to integrate CT and students' assets in core courses to support critical analysis and potential action in students' respective communities. Furthermore, experiences

such as STEM + C3 prepare teachers to advocate for the expansion of CS course offerings within their school sites, possibly leading to new types of computing units and courses that attract underrepresented student populations. The integration of CT within math and science classrooms provides students with exposure and confidence to pursue CS courses.

The STEM + C3 program will continue to be iterated upon and refined as it moves into its third year. It fills a void in a creative, novel way that is suited specifically for California. The field of CT education is currently in a similar place to the NGSS professional development in 2013, where a clear set of standards and framework had been laid out but education programs, professional learning providers, and educators lacked concrete tools and exemplars demonstrating authentic three-dimensional learning, where the disciplinary content knowledge, practices and cross-cutting concepts drive instruction. To continue this work, teachers will need curricula that model thoughtful integration of CT into math and science classrooms. There is a need for professional learning spaces in which educators critically examine the curriculum and its relation to their specific student population; teachers will need time and support to modify this curriculum for their particular context. CS education needs to better address the social inequities within computing and society at large. As we work toward the vision of “CS for All”, frameworks such as CT for Equity provide an opportunity to consider how we might go about doing this difficult work.

Acknowledgment

We would like to thank the invaluable intellectual labor and support offered by Suyen Machado, Monica Casillas, James Molyneux, and Beth Simon in the formation of the CS courses and the professional learning support provided by the UCLA Science project. This work could not be done without our amazing district liaisons, teacher candidate residents, and partner teachers who continue to inform this project. This work is supported by a grant from the US Department of Education (Award # U336S190038). The views and opinions expressed herein are those of the authors only, and do not represent the official views and opinions of the Dept. of Education.

Glossary

Asynchronous learning A course modality where instruction and learning do not occur in the same geographic location or the same time.

Disciplinary-Based Education Research (DBER) Systematic, empirical investigation to test theories relevant to teaching and learning within a single discipline, informed by disciplinary expertise

Evidence-based The practical application of rigorously evaluated current research to a concept, strategy, or design

Humanistic STEM (H-STEM) A blending the study of science, technology, engineering, and mathematics with interest in, and concern for, human affairs, welfare, values, or culture

Scholarship of Teaching and Learning (SoTL) Systematic, applied research to test theories relevant to teaching and learning, applicable across disciplines

Introduction

High profile STEM organizations have become vocal in advocating for improvements in STEM teaching and learning (Jamieson and Lohmann, 2012; Olson and Riordan, 2012). While STEM course enrollments have dropped slightly in the last two years, online course enrollments saw significant growth in this time frame (National Center for Education Statistics, 2019, 2020). There has been increased attention to best practices not just in online learning, but specifically in teaching STEM disciplines online. While the event was ultimately canceled due to the COVID-19 pandemic, The American Chemical Society's Biennial Conference on Chemical Education had a symposia titled "Advances in Online Chemistry Education". The 2020 Electronic Conference on Teaching Statistics (hosted by the Consortium for the Advancement of Undergraduate Statistics Education) held a panel for engaging diverse audiences through online learning.

The scholarship of teaching and learning (SoTL) offers a route to improve STEM teaching and learning, with notable benefits to students, instructors, and institutions. SoTL is often considered to have originated in 1990 with Ernest Boyer's book *Scholarship Reconsidered: Priorities of the Professoriate*. This book argued for the value of four aspects of scholarship, including scholarship of discovery, scholarship of teaching, scholarship of integration, and scholarship of application. While some disciplines had previously valued educational research, this public call to value the scholarship of teaching in higher education was heard; SoTL has flourished in the decades since. Two widely cited sources for best practices in SoTL are outlined in Table 1. SoTL activities generate evidence-based models of practice for colleagues and establish high-quality education for students (Bernstein, 2013).

Table 1 Best practices in SoTL.

	Glassick et al. (1997)	Felten (2013)
Focus	Clear goals	Inquiry focused on student learning
Literature review	Adequate preparation	Grounded in context
Methodology	Appropriate methods	Methodologically sound
		Conducted in partnership with students
Data analysis	Significant results	
Discussion	Reflective critique	
Dissemination	Effective presentation	Appropriately public

SoTL adheres to scholarly work standards as other forms of scholarship, requiring disciplinary expertise, innovation, replication, peer review, and impact (Diamond, 2002). The SoTL research process is similar to research in STEM Fields. SoTL research is a systematic inquiry, proceeding from identifying a problem, establishing a theoretical framework, designing the study using appropriate data collection methods (qualitative, quantitative, or mixed methods), analyzing data rigorously using statistical analysis where appropriate, and disseminating the work. Ethics must be considered in SoTL work as most studies will involve human subjects, necessitating review by an Institutional Review Board. Because the key goal of SoTL is to transform teaching in higher education (Huber and Hutchings, 2005), accessible dissemination is a key step in the SoTL process. Dissemination options are growing, including teaching conferences and journals. Some journals offer open access publication without large article processing charges. As with dissemination in all disciplines, venues must be thoroughly evaluated for quality and impact.

Felten argues that SoTL is a signature pedagogy of educational development that enacts practices, values, and assumptions in a way that aligns purpose and practice (Felten and Chick, 2018). Despite the documentation of effective pedagogies and interventions in traditional STEM teaching and learning, the rate of adoption and scale-up has been limited (Borrego and Henderson, 2014). It is reasonable to assume that online STEM faces the same limitations.

Despite the benefits of SoTL, some institutions have experienced the SoTL paradox, where the increased recognized value of SoTL work has not been matched with recognition for SoTL efforts in formal reward systems like promotion and tenure (Walker et al., 2008). Disciplinary-based education research (DBER) has also seen growth, and mismatched recognition within STEM (Dolan et al., 2018). This is in spite of many faculty engaging in SoTL and DBER research. According to one study that included STEM and non-STEM disciplines, nearly half of faculty promotions at a research university included at least one SoTL artifact (Marcketti and Freeman, 2016).

Solutions to the SoTL paradox are likely unique to the goals of an institution and, even within an institution, aspects of faculty promotion and tenure like load balance can vary (Cruz et al., 2009). Some institutions permit unequal value weighting of SoTL scholarship compared to scholarship of discovery for promotion and tenure decisions (Cruz et al., 2009). At one institution, the Engineering & Technology Department supported equal valuation both pre- and post-tenure while GeoSciences and Natural Resources Department supported unequal valuation pre-tenure with equal valuation post-tenure (Cruz et al., 2009). While some discussion of support for SoTL for online STEM faculty exists (Herman and Butler, 2019), at this time, little information is publicly available about the support for SoTL research (and the SoTL paradox) for tenured or tenure-track STEM faculty teaching fully online.

At Embry-Riddle's Worldwide Campus, the College of Arts and Sciences took proactive measures to address the SoTL paradox. Previously, the Math, Physical, and Life Sciences Department was comprised of faculty teaching STEM general education courses in mathematics, chemistry, life sciences, physics, computer science, and statistics, as well as applied sciences courses. While many of the faculty in the department were non-tenure track, those faculty on the tenure-track were engaged in SoTL and DBER research. To honor the research and teaching interests of faculty, the department was divided in 2019 to form the Department of STEM Education and the Department of Applied Sciences. Tenure line faculty in the Department of STEM Education could focus more on educational research in STEM and those in the Department of Applied Sciences would focus on disciplinary research. In 2019, Promotion and Tenure (P&T) policy documents were prepared and approved that support STEM-focused SoTL and DBER activities by permitting faculty to publish scholarship in professional spaces "as appropriate for the research focus defined by the candidate". Furthermore, this new P&T policy does not suggest unequal weighting of these efforts with STEM disciplinary works; faculty autonomy is supported, stating "no individual pursuit of research is the same as another". Further, according to this policy, publication venues must be refereed and demonstrate selectivity, prestige, and impact, as evidenced through bibliometrics. Many SoTL and DBER publication venues meet these criteria. The following section will present an analysis of various research artifacts generated by tenure-track faculty within the Department of STEM Education.

Analysis of recent SoTL and DBER research artifacts in STEM

Science

In Faulconer et al. (2019), two Department of STEM Education faculty collaborated to explore the influence of combining two practices—providing multiple attempts on summative assessments and providing high-quality immediate feedback—to explore the impact on student behaviors and performance. While this study focused on a Chemistry course, the concept is transferable to additional STEM disciplines. Therefore, the authors published in a SoTL journal rather than a DBER journal.

This paper meets Felten's good practices in SoTL (Felten, 2013). The work is an inquiry focused on student learning, with the specific goal of improving performance on summative assessments. The work is grounded in context by building on existing, relevant theory and prior research on multiple attempts and feedback. The work is methodologically sound through its use of a quasi-experimental design. The work is conducted in partnership with students in several ways. The study was reviewed by the institutional review board. An undergraduate student co-authored the paper. Additionally, the results have been communicated to students to encourage use of the multiple attempts. Finally, the conclusions of this work are appropriately public, published in a quality journal (2019 Metrics: Impact Factor 2.136, CiteScore 3.7, SNIP 1.985) managed by the reputable publisher Taylor & Francis.

The researchers used the learning management system to provide timely, actionable, specific feedback to students on their online quizzes. The option to re-take the quiz, pulling questions randomly from pools aligned with the learning objectives, turned the feedback into feedforward by allowing students to apply the knowledge gained. Each quiz attempt was unique, students earned their highest score from the multiple attempts, and there was no penalty for failure to use multiple attempts. They reported the

following conclusions: (1) students who did not initially earn an A were more likely to try again, (2) students tended to perform better on their second attempt in both chemistry lecture and laboratory courses (Faulconer et al., 2019). Interestingly, students who used two attempts did not outperform those who only used one attempt (Faulconer et al., 2019). It can be inferred, then, that the multiple attempts format allows students to close the performance gap. This is, however, a notable time investment for students, with those who used multiple attempts spending approximately twice as long on the assessment task as those who only used one attempt (Faulconer et al., 2019). In light of the outcome that time on task alone was not a good predictor of assessment performance (Faulconer et al., 2019), it further supports the notion that this pedagogical choice supports closure of a performance gap for students.

The impact of this research can be evaluated through several means, though traditional means such as the number of citations may not be appropriate (Dolan et al., 2018). The ultimate goal of SoTL and DBER is to improve student learning. Reach to practitioners is key, which cannot be evaluated by a citation count. For example, the most-downloaded article from the *Journal of College Science Teaching* has been accessed 11,682 times but, according to Google Scholar, this work has garnered 1330 citations. As of September 1, 2020, the Faulconer et al. (2019) article has an Altmetric of 2, with 210 views reported by the journal and 73 downloads reported by Scholarly Commons.

Statistics

In Bourdeau et al. (2017), one Department of STEM Education faculty member collaborated with colleagues within another department in the College of Arts and Sciences to explore the influence of targeted STEM educational videos on student understanding of key concepts (Bourdeau et al., 2017). While this pilot study took place in an introductory research course, many of the difficult topics targeted for video resource development were focused on experimental design and data analysis concepts related to statistical concepts. Specifically, videos were developed on the topics of categorical versus numerical variables, selecting an appropriate statistical test, p-values, and confidence intervals. While this work was largely research and statistics-focused, the idea is theoretically transferable to other disciplines. Therefore, this work was published in a SoTL journal rather than a DBER journal. Unfortunately, the generalizability of this study was limited due to a low response rate. The authors point to the potential stumbling blocks for implementing these types of interventions. For example, the non-mandatory nature of the videos may have reduced student access and perceived utility of the resource.

Felten's five good practices in SoTL are evident in this publication. This study directly focused on improving student learning by providing additional multimedia resources to support the most-difficult content topics in the course. This work is grounded in context, built upon previous research that demonstrates efficacy of multimedia use in the classroom. The authors ground their work in the theory of self-directed learning. Design-based research is a valid method for performing SoTL research. The student perspectives were measured using voluntary surveys. While this study secured institutional approval to protect human subjects, it goes beyond this minimum expectation by including students as partners in the inquiry through collection of their perspectives of the multimedia intervention. Finally, this work is appropriately public, published in an open-access journal indexed by ERIC and the Directory of Open Access Journals. While the journal is not listed in Scopus or Cabell's, the journal is published by the Eurasian Society of Educational Research.

While this paper has only garnered one citation, as of September 24, 2020, the article has been viewed by 307 people and downloaded by another 478 people, reported by the journal. These statistics demonstrate a reach to practitioners, which was the goal of the authors.

Cross-disciplinary

In Faulconer et al. (2021), two Department of STEM Education faculty collaborated with a colleague within another department as well as a colleague external to the institution to explore the use of course video trailers to contextualize the general education competencies, explaining how general the general education course was valuable to students in their academic and professional lives. This study included courses across multiple disciplines, including two mathematics courses, three science courses, an introductory research methods course, and an English composition course. The videos produced followed best practices, including use of a singular message focused on context, short duration (one to 4 min), and high production value (Goudsouzian, 2018; Truell, 2018). The cross-disciplinary nature of this work justified publication in a SoTL journal.

This paper meets Felten's good practices in SoTL. While this study did not focus specifically on disciplinary knowledge or skill development, it did explore student attitudes that connect to learning, which meets Felten's definition of inquiry focused on student learning (Felten, 2013). The work was grounded in relevant theory regarding the influence of course first impressions and contextualization on student attitudes, persistence, and performance (Wong, 2016; Wachen et al., 2011). The study was methodologically sound, using survey research to explore student opinions and attitudes regarding the course trailers. This research aligned with basic tenets of human subject research and was reviewed by the Institutional Review Board. Beyond that, the nature of the research methodology inherently engaged students in the inquiry process. This work is appropriately public, published in a quality journal published by Penn State University Press since 1999 (2019 Metrics: Impact Factor 0.23, CiteScore 0.4, SNIP 0.148).

Undergraduate students often misunderstand the nature and value of general education courses for their academic and professional growth. In this work, the researchers developed video course trailers that were designed specifically to contextualize the course in terms of a specific institutional general education competencies (i.e., transferable skills) developed throughout the course. Through the

videos, the researchers aimed to improve contextualization through four specific means: posing challenges and questions, reference to additional resources, redundant iterations of usefulness, and application of cited best practices in course trailer development. The influence of the videos was measured by comparing the change in student perceptions of the fit of the general education course into their academic and professional plans once videos were placed into the learning management system for each course. The study reported that, while a strong understanding of the fit of the general education course in both their academic and professional plans existed prior to implementation of course video trailers, there was a statistically significant improvement in this understanding through implementation of video course trailers (Faulconer et al., 2021). It is important to note that the predominance of physics students in the data may have skewed the results due to the aeronautical orientation of the university studied. However, taken in aggregate terms, the results seemed to support using videos to reinforce course value to students' personal and professional lives. Having just been published, the impact of this work is yet to be seen. Based upon the bibliometrics for the journal, notable citations of this work are not expected. While the readership for the journal is not publicly available, the journal is indexed in IBZ, MLA International Bibliography, and SCOPUS, making it available through certain institutional library collections.

Integration of research

The SoTL research led by faculty from ERAU Worldwide's Department of STEM Education has aided in course assessments and improvement of teaching practices. The concept of multiple attempts with feedforward has been implemented in six online STEM courses, including chemistry, environmental science, biology, and an interdisciplinary science course. Research that demonstrates applicability across multiple STEM disciplines is currently under review. The video course trailer study generated script templates and a best practices list that has been used to generate and evaluate videos in STEM and non-STEM courses in three other departments.

Demonstrating integration of research with service, a 2020 study led by the Department of STEM Education faculty reported on a survey of safety culture in academic laboratories (Faulconer et al., 2020). This lead author also serves as the Chair of the institution's Academic Safety Committee. This study helped support administrative actions to improve safety training, ultimately resulting in the development and launch of a fully online, asynchronous safety training for both students and faculty. This study also led to the subsequent publication of tandem editorials written in collaboration with faculty in another department on the topic of supporting safety culture in academia, including safety communication barriers (Faulconer and LeNoble, 2020) and giving a voice to faculty (LeNoble and Faulconer, 2020).

Another example of high-level integration started with two studies, with the first being a comparison of interests in and barriers to undergraduate research between distance and in-person students (Faulconer et al., 2020e) and the follow-on study comparing the same in online and residential faculty (Faulconer et al., 2020d). These studies laid the foundation for a successful funding proposal through the National Science Foundation's Improving Undergraduate Stem Education: Education and Human Resources program (NSF 19-601), which supports novel, creative, and transformative approaches to knowledge creation in undergraduate STEM teaching and learning. This project, launched in October 2020, will establish key supports for undergraduate research in a fully online engineering technology bachelor degree program with the goal of improving degree retention and persistence as well as improving STEM identity and attitudes. Supports include long-term research mentorship, synchronous and asynchronous online research skills workshops, online faculty professional development for research mentorship and supervision, and the development of a structured 9-week research-focused independent study course. This project supports teaching and service activities for multiple faculty members and will generate additional research scholarship.

Faculty within the department have also collaborated across departments to develop critical emphasis on humanistic STEM (H-STEM). A modern approach is humanistic STEM, defined as "a path blending the study of science, technology, engineering, and mathematics with interest in, and concern for, human affairs, welfare, values, or culture" (Bourdeau and Wood, 2019). Early work in this area explored the influence of infusing humanities into online STEM courses on student perceptions of connections between the course content and cross-disciplinary perspectives (Faulconer et al., 2020c). This effort led to efforts to infuse STEM into humanities courses, including efforts in a History of Aviation course. Faculty received funding from the Synergistic Undergraduate Mathematics via Multi-Institutional Interdisciplinary Teaching Partnerships (SUMMIT-P) grant to develop two math courses aligned with H-STEM practices, Learning to Reason: Art and Quotient and Learning to Reason: Commerce and Flux. The courses are fully online asynchronous courses taught over 9 weeks. Both courses were developed by a multidisciplinary team. Planned research will collect data from these courses to provide evidence to support H-STEM as a valid approach in teaching and learning. Departmental faculty are also seeking external funding to develop an H-STEM minor, including courses like Digital Humanities as well as Data Visualization and Storytelling with Data. Furthermore, the funding proposal also seeks to establish an H-STEM center to support a consortium of institutions engaged in H-STEM research.

Conclusion

While there has been a long period showing a positive growth trend in online education, this was significantly increased in 2020. We cannot assume faculty expertise in online pedagogy, learning management system use, and online curriculum design. There has been long-term resistance to offering STEM courses online. The provision of evidence-based models of excellence can support widespread adoption of the online modality for STEM courses among administrators and educators.

However, some STEM faculty may experience a SoTL paradox, where they do not have full academic freedom to pursue research lines in this area. Without administrative support through actions and policies, faculty may not see a good return on investment for their time on SoTL scholarly efforts. These research efforts offer benefits for students, faculty, and institutions. As evidenced from the research analyzed in this article, the SoTL research performed by fully online STEM faculty within the Department of STEM Education at Embry-Riddle's Worldwide Campus meets best practices and has implications beyond dissemination. The works supported improved teaching by providing evidence-based models of excellence in instructional design and teaching practices. Furthermore, SoTL research by STEM faculty supported high-level service activities for multiple STEM and non-STEM faculty members. As important as discipline-specific research is to the growth in the body of knowledge, SoTL research will help ensure that knowledge is effectively passed to the students we serve.

Introduction

The design of any product or environment involves myriad considerations—research basis, purpose, safety and other standards, flexibility, sustainability, and cost, to name a few. Many current design practices focus on the average user. In contrast, UD sets the goal to design products and environments suitable for individuals diverse with respect to gender identity, race, ethnicity, age, socioeconomic status, ability, learning style, and other characteristics. Originally applied to architecture and consumer product design, UD has more recently emerged as an approach for addressing diversity, equity, and inclusion in the design of IT as well as a wide range of on-site and online, formal and informal learning offerings at all educational levels.

Although student bodies at all levels have become increasingly diverse with respect to race, ethnicity, gender identity, ability, and other characteristics, significant gaps exist in the achievement of some postsecondary degrees that include those in STEM for marginalized groups such as students with disabilities compared with their peers without these identities ([National Science Foundation, 2021](#)). However, success stories demonstrate that opportunities do exist for students who successfully overcome barriers imposed by inaccessible facilities, curricula, websites, digital files, instructional practices, and other aspects of educational offerings ([DO-IT, 1993–2021](#); [Stern and Woods, 2001](#)). Factors that impact retention of a diverse STEM student body occur at both the individual (e.g., socioeconomic status, study skills) and institutional (e.g., institutional policies, instructional practices) levels ([Allen and Anderson, 2020](#); [Berge and Huang, 2004](#); [Braxton et al., 1997](#); [Tinto, 1993](#)). The author of this chapter addresses institutional issues by focusing on the design of formal and informal STEM educational offerings that are accessible to and inclusive of students with diverse characteristics, including disabilities.

The discussion below elucidates some of the challenges faced by STEM students with various levels of physical, sensory, learning, attention, and communication abilities and shares examples of ways an instructor or institution can proactively ameliorate potential barriers to these students.

- *Visual differences.* Web content with certain color combinations presents a barrier to access for people who are color-blind; webmasters can avoid this by ensuring that content and navigation do not require the distinction of colors alone. In a similar vein, since screen reader technology can only read aloud text, individuals who are blind cannot make sense of content within images; by including alternative text descriptions for these images, webmasters can bypass this barrier. Individuals who have low vision and use software to enlarge screen images can view only a small portion of content at one time; this problem is minimized when web pages are uncluttered and use large text and plain backgrounds.
- *Hearing differences.* Audio content is unavailable to students who are deaf; this barrier is avoided when videoconferencing, videos, and video clips are captioned or transcribed and sign language interpreters and real-time captions are provided.
- *Physical differences.* Some STEM labs and other facilities are not comfortable for students who are larger than average; providing a few larger chairs can solve this problem. Lab stations that are not wheelchair-accessible cannot be used by some students and instructors; designing workspaces with adjustable height surfaces is one way to address this problem. Some individuals use alternative input devices that emulate the functions of a standard keyboard but not a mouse; instructors can avoid erecting barriers by using websites and software applications that can be operated with the keyboard alone.
- *Learning differences.* Course content delivered in a single mode, such as by lecture, creates challenges to access for students with diverse learning styles, strengths, and preferences; offering learning opportunities in multiple ways (e.g., orally, in printed materials, in video presentations, in discussions) can address this access issues. Online courses that change formats quickly or crowd too much content on the screen can create confusion or overwhelm students who are neurodiverse (e.g., students on the autism spectrum, with some types of learning disabilities or attention deficits); this problem is resolved when instructors present content in consistent formats and patterns and on uncluttered pages. When time provided to complete an assignment is inadequate, students with learning disabilities that affect processing speed are placed at a disadvantage; presenting assignments

early allows all students to demonstrate their knowledge. Some students with learning disabilities that affect their ability to interpret written text are at a disadvantage when written materials are the only option for gaining content; offering these readings in electronic formats such as HTML or accessible PDF so that it can be read aloud with text-to-speech software benefits these students.

- *Attention differences.* Most classes include students with a wide range in attention spans; some may find it difficult to pay attention to a lecture or engage in a lab. Instructors can avoid erecting barriers to these students by providing printed instructions or an easy-to-follow lecture guide.
- *Communication differences.* Some communication differences are related to autism, language proficiency, and abilities to speak or hear. Communication methods that do not require the ability to hear or speak and allow for differences in time needed to compose a thought (e.g., Email, engagement in an online discussion forum) allow all participants to engage.

Addressing the role that the designs of physical spaces, courses, technology, and other products play in erecting barriers to some people supports social models of disability—e.g., with respect to gender identity, socioeconomic status, race, ethnicity, body size, and ability—as simply a normal state of the human experience. Some consider that “impairment is an individual limitation, while a disability is a socially imposed restriction. Not being able to walk is an impairment but lack of mobility is a disability (a socially created situation)” (Seale, 2013, p. 23). Not being able to see is an impairment, but not having access to website content using a screen reader is the result of poor web design. A wheelchair user unable to reach the equipment in a makerspace is a result of the inflexible design of the furniture and layout.

The accommodation approach to access

Approaches for providing access to education for individuals with disabilities have evolved over time. In the past some individuals with disabilities were excluded from educational opportunities or learned in environments separated from those for other students. In the US, increased demands for the inclusion of otherwise qualified students with disabilities in all learning opportunities came from injured veterans returning from World War II who were eligible for college funding through the GI Bill, parents who wanted more academic options for their children, and those inspired by the civil rights movements for women and minorities to extend similar rights to people with disabilities. These efforts led to mandates that protect the rights of children with disabilities. The Individuals with Disabilities Education Act (IDEA, 2004) ensures that all children with disabilities are entitled to a free appropriate public education to meet their unique needs and prepare them for further education, employment, and independent living. These efforts also led to more general civil rights protections that apply to all students with disabilities in formal and informal educational opportunities at all academic levels—Section 504 of the Rehabilitation Act of 1973 as well as the Americans with Disabilities Act of 1990 (ADA) and its 2008 Amendments (ADAA), which considers a person with a disability to be any individual who

- has a physical or mental impairment that substantially limits one or more major life activities of such individual;
- has a record of such an impairment; or
- is regarded as having such an impairment (ADAA, Section 12102).

According to the ADA, no otherwise qualified individual with a disability shall, solely by reason of that disability, be excluded from, denied the benefits of, or subjected to discrimination under educational programs and other covered entities. *Qualified* with respect to education available to the public means an individual with a disability who, with or without reasonable modifications to rules, policies, or practices, the removal of architectural, communication, or transportation barriers, or the provision of auxiliary aids and services, meets the essential eligibility requirements for the receipt of services or the participation in activities (ADA, Section. 12101). Similar laws that protect the rights of people with disabilities have been enacted in countries around the world.

Using an accommodation approach for addressing the inaccessible design of program offerings is deeply rooted in the culture of most educational institutions. An *accommodation* occurs when an adjustment or modification is made to a product or environment so that it is accessible to an individual with a disability. A focus on accommodations is grounded in a medical model (or deficit model) of disability, in which a professional identifies an individual’s functional limitations and prescribes a cure, rehabilitation, or adjustments that allow this person to fit into an established program (Jones, 1996; Loewen and Pollard, 2010). In K-12 education, parents, teachers, and counselors work together to ensure the student has an appropriate education; in higher education, typically the student must provide documentation of a disability to a specified office at the institution and request accommodations. The institutional representative approves accommodations considered reasonable and, with the permission of the student, shares this information with appropriate faculty and staff who implement the accommodations. Examples of accommodations include materials in alternate formats, extra time on assignments and exams, sign language interpreters and real-time captioners, and movement of classes to wheelchair-accessible locations.

It is estimated that most adult students potentially eligible for accommodations choose not to seek accommodations; similarly, often parents of students with disabilities in informal learning programs do not request accommodations. When asked why, some individuals with disabilities report embarrassment, concerns about discrimination, and cumbersome request processes. Negative aspects that occur when an accommodation-only approach is applied include the following:

- The process for securing accommodations marginalizes students with disabilities by requiring a segregated process for gaining access.
- The value associated with an accommodation does not extend to students with disabilities who choose not to self-disclose nor to other students in a class who might benefit from it.
- An accommodation does not always result in content and experiences equivalent to those of other students.
- An accommodation for one student does not in and of itself make an activity more accessible to other students.

The universal design approach to access

A variety of terminology—useable design, accessible design, inclusive design, design for all, barrier-free design, user-centered design, human-centered design, sustainable design, universal access, universal design—has been used to label proactive efforts that have been made to proactively design products and environments that avoid the creation of barriers to some people. They have in common a paradigm shift in design approaches from a focus on the average or deemed typical user to consideration of a broad range of human characteristics (Myers et al., 2013). Accessible design practices often limit their scope to access issues faced by people with disabilities. Useable design takes into account how easily users can learn how to operate a product, achieve their goals, and remember how to perform tasks when they return to the product at a later time. Not all accessible products are useable. For example, applications software could offer keyboard options in such a way that a person who is blind could in theory navigate it with a screen reader, but, make the product unusable because the options are too confusing for screen reader users. Inclusive design implies that a single product is appropriate for all potential users. However, designs that are technically accessible and useable may not be inclusive. For example, an entrance to a building that has stairs and a separate ramp for wheelchair users is accessible and useable but is not inclusive because all individuals approaching the building do not enter in the same way. A more inclusive design is a sloping ramp to the entrance that allows people of all abilities to approach and enter the building together.

Universal design (UD)—arguably the most comprehensive of all proactive approaches (Seale et al., 2020)—creates products that are accessible, useable, and inclusive, as illustrated in Fig. 1.

UD has a long and rich history. Marc Harrison (1928–1996), a professor of industrial engineering at the Rhode Island School of Design, was a pioneer in what was later called UD. Insight and inspiration for Harrison’s work came from engaging in years of rehabilitation after sustaining a traumatic brain injury as a child. He, like universal designers today, challenged design practices that focus on individuals of average ability and promoted the notion that products and environments should take into account the diversity of abilities in human beings. One of his many designs was a food processor with large and easily pressed buttons, large handles, and large, high-contrast labels that made it useable by more people (Hagley Museum and Library, n.d.). In the late 1970s, Ronald Mace—a wheelchair user, architect, product designer, and educator—coined the term universal design. At the Center for Universal Design (CUD) at North Carolina State University, he defined UD as “the design of products and environments to be useable by all people, to the greatest extent possible, without the need for adaptation or specialized design” (CUD, n.d.). He and his colleagues demonstrated how UD features could be integrated into a product or environment in such a way that they do not stand out and thus foster the social integration of people with disabilities and other marginalized groups. An example of UD is a sidewalk that has curb cuts to make it useable by people who are walking, using wheelchairs and walkers, pushing baby strollers, and rolling delivery carts. The common thread of all UD applications is that a diverse group of users can fully benefit from a product or environment in an inclusive setting (National Council on Disability, 2003).

Similarly, when instructors apply UD to a postsecondary course, they consider the great diversity of potential students. Considerations include level of ability to move, see, hear, read, learn, and process information; stature; age; race; ethnicity; culture;

Fig. 1 Characteristics of a UD strategy: accessible, useable, and inclusive. Source: Burgstahler (2015, p. 15).

socioeconomic status; learning style and preference; dexterity; native language; intelligence; and gender. Considering that most characteristics (e.g., the ability to hear) can be measured on a continuum, the traditional view of a person “having a disability” or “not having a disability” is overly simplistic. Everyone has a unique combination of abilities that can change over the course of a lifetime.

In contrast to the limited accommodation approach to access, the UDE Framework

- is comprehensive enough to address issues of diversity, equality, accessibility, social integration, and community;
- goes beyond the design of learning activities to provide guidance for making physical spaces, services, and technology that make education more welcoming to, accessible to, and useable by all students;
- can be applied incrementally; and
- can be used to guide practices in specific academic areas such as those in STEM.

The UDE framework

A framework for the scope of any UD application area was developed by the author of this article (Burgstahler, 2020)—it includes scope, definition, principles, guidelines, practices, and process, as visualized in Fig. 2. The Framework can be fleshed out for any and all UDE applications. A scope could be narrowly focused (e.g., distance learning in STEM) or broadly focused (e.g., all design practices for teaching and learning, services, technologies, and physical spaces) design practices at a postsecondary institution) or more narrowly focused (e.g., courses in a specific academic field). The following paragraphs flesh out the UDE Framework for the scope of applications in this chapter, all UDE applications relevant to STEM, including on-site, online, and hybrid; formal and informal; and online and on-site offerings.

After the basic definition of UD was established, in the mid-90s, with funding from the U.S. Department of Education, a group of product developers, architects, environmental designers, and engineers at CUD established a set of seven principles of UD and related guidelines to consider in the design of any product or environment (CUD, n.d.).

- *Equitable use.* The design is useful and marketable to people with diverse abilities.
- *Flexibility in use.* The design accommodates a wide range of individual preferences and abilities.
- *Simple and intuitive use.* Use of the design is easy to understand, regardless of the user’s experience, knowledge, language skills, or current concentration level.
- *Perceptible information.* The design communicates necessary information effectively to the user, regardless of ambient conditions or the user’s sensory abilities.
- *Tolerance for error.* The design minimizes hazards and the adverse consequences of accidental or unintended actions. Discourage unconscious action in tasks that require vigilance.
- *Low physical effort.* The design can be used efficiently, comfortably, and with a minimum of fatigue.
- *Size and space for approach and use.* Appropriate size and space are provided for approach, reach, manipulation, and use regardless of the user’s body size, posture, or mobility (Story et al., 1998, pp. 34–35).

Fig. 2 Components of a UDE framework. Source: Burgstahler (2020, p. 36).

These general principles and guidelines can apply to any design discipline (Story et al., 1998, p. 32). From this foundation, the authors also expected that practitioners would develop design standards and compliance tests for specific fields. For example, principle 5, “Tolerance for error,” can be applied to a formal or informal online course—even though offering courses online was a rare practice when the principle was written—by providing helpful feedback that redirects a student who makes a specific selection error while engaging with the curriculum.

Some researchers and practitioners have used the seven principles of UD as a foundation on which to build additional principles, guidelines, and lists of promising practices to help practitioners implement UD in specific situations. With respect to IT, Vanderheiden and Vanderheiden (1992) developed specific guidelines for information technology. Later, IT accessibility leaders organized by the World Wide Web Consortium worked together to develop the Web Content Accessibility Guidelines (WCAG). These Guidelines dictate that all information and user interface components follow four guiding principles:

- *Perceivable*: Users must be able to perceive the content, regardless of the device or configuration they’re using.
- *Operable*: Users must be able to operate the controls, buttons, sliders, menus, etc., regardless of the device they’re using.
- *Understandable*: Users must be able to understand the content and interface.
- *Robust*: Content must be coded in compliance with relevant coding standards in order to ensure its accurately and meaningfully interpreted by devices, browsers, and assistive technologies (World Wide Web Consortium, 2018).

Although developed for web design, the WCAG principles, guidelines, and success criteria can also be applied to curriculum and materials, software, and other technologies (World Wide Web Consortium, 2013). Accessible practices that emerge from WCAG include providing alternative text to describe the content in images, captioning and audio describing videos, using headings at appropriate levels within documents and websites, using link text that describes its destination, and ensuring that the product can be operated with a keyboard alone.

Many UD-inspired approaches have emerged to specifically address instructional applications that include formal and informal learning (Burgstahler, 2015; Roberts et al., 2015). Each rests upon a common finding in educational research—learners are diverse with respect to their abilities, learning preferences, and responses to instruction. The most common UD-inspired principles applied to the design of curriculum and instruction are those developed by the Center for Applied Special Technology (CAST, n.d.). Applying Universal Design for Learning (UDL) principles requires that instructors offer students multiple means of engagement, representation, and action and expression throughout their learning experiences, as defined below.

- *Engagement*: For purposeful, motivated learners, stimulate interest and motivation for learning.
- *Representation*: For resourceful, knowledgeable learners, present information and content in different ways.
- *Action and expression*: For strategic, goal-directed learners, differentiate the ways that students can express what they know (Center for Applied Special Technology, 2018).

The combination of principles that underpin UD, WCAG, UDL can be applied to the design of all physical, technological, and pedagogical aspects of formal and informal, hybrid and fully online, and synchronous and asynchronous learning (University of Washington, n.d. b). Employing practices supported by this combination of principles for online learning technology and pedagogy ensure that

- students have multiple ways to gain knowledge, demonstrate what they have learned, and interact; and
- each practice and technology is accessible, useable, and inclusive.

Instructors can apply UD principles to

- the overall design of the course (e.g., choosing to employ accessible learning management system (LMS) features, carefully organizing the course so that it is easy to follow),
- curriculum (e.g., using accessibly designed documents, captioning videos, developing clear instructions for assignments),
- communication methods (e.g., allowing students to choose communication methods when meeting one-on-one with the instructor, clearly describing the questions to be addressed in a discussion thread), and
- the design of specific assignments (e.g., giving small group members guidelines for conducting accessible meetings, requiring students apply UD to the design of their projects).

It is good news to many instructors that UD, UDL, and WCAG principles do not replace principles of good design of STEM instruction, curriculum, and facilities. Rather, UDE complements them, in the same way that applying UD complements other accepted practices for sidewalk design. Similarly, applying UD does not require abandonment of adopted teaching and learning philosophies, theories, and practices such as cooperative learning, constructive learning, and learner-centered instruction (Burgstahler, 2020). Instead, STEM instructors can apply UDE to ensure that they employ multiple teaching practices and that each practice is accessible, useable, and inclusive. A reasonable approach for creating inclusive online learning pedagogy is for online learning designers and instructors to select evidence-based instructional practices and then apply relevant UD, UDL, and WCAG principles to each practice. This process is presented in Fig. 3.

Fig. 3 An approach for applying UD to STEM curriculum and instruction.

UDE guidelines and practices in STEM education

Examples of formal and informal STEM education practices supported by the fourteen UDE principles are presented in **Table 1**.

There is no shortage of guidance to help course instructors develop formal and informal STEM offerings to be accessible to all students (Burgstahler, 2011, 2012, 2015, 2021; Higgins and Maxwell, 2021; Miller and Lang, 2016; Sweet, 2018). For example, the Access to Informal Science Learning (University of Washington, n.d. a) project, AccessISL, at the University of Washington developed a checklist of considerations for designing accessible and useable informal STEM learning (DO-IT, 2022). Addressing the questions presented in the checklist provides a good starting point for making informal learning activities, facilities, and resources accessible to and inclusive of everyone. A few examples follow.

Planning, Policies, and Evaluation. Consider disability and other diversity issues as you plan and evaluate offerings and activities.

- Are people with disabilities, racial and ethnic minorities, men and women, young and old, first generation, individuals with low income, and other groups represented in the project planning processes in numbers proportional to those of the whole campus or community?
- Are disability-related access issues and other diversity issues addressed in data collection, evaluation plans, and instruments?

Table 1 An example of a UDE practice supported by each UDE principle.

UDE principle	Example of UDE practice in STEM education
UD 1. Equitable use	<i>Overall design.</i> In designing and delivering all aspects of a science learning opportunity the designer or instructor maximizes its accessibility, usability, and inclusivity for students with diverse abilities, gender identities, races, ethnicities, interests, and other characteristics.
UD 2. Flexibility in use	<i>Science museum.</i> A bioengineering exhibit allows a visitor with diverse abilities to choose to read or listen to descriptions of the contents of display cases and to engage in hands-on activities.
UD 3. Simple and intuitive	<i>Assessment.</i> Testing in a computer science course is conducted in a predictable, straightforward manner.
UD 4. Perceptible information	<i>Lab.</i> An emergency alarm system in a biology lab has visual, aural, and kinesthetic characteristics.
UD 5. Tolerance for error	<i>Instructional software.</i> A physics tutorial provides guidance when a student makes an inappropriate selection.
UD 6. Low physical effort	<i>Curriculum.</i> Forensic science educational software includes on-screen control buttons that are large enough for students with limited fine motor skills to select.
UD 7. Size and space for approach and use	<i>Makerspace.</i> An adjustable table and flexible work area is useable by students who are right- or left-handed and have a wide range of physical abilities.
UDL 1. Multiple means of engagement	<i>Course.</i> Multiple examples in an environmental science class ensure relevance to a group with diverse interests.
UDL 2. Multiple means of representation	<i>Curriculum.</i> Students are shown a captioned video, assigned textbook reading, and given physical models to manipulate in order to learn a mathematics concept.
UDL3. Multiple means of action and expression	<i>Course project.</i> An assigned project in a general science class optimizes individual choice and autonomy.
WCAG 1. Perceivable	<i>Website.</i> A person who is blind and using a screen reader can access the content in images for an engineering course because text descriptions of content in images are provided.
WCAG 2. Operable	<i>Learning management system (LMS).</i> A person who cannot operate a mouse can navigate all content and operate all functions within a LMS used to deliver STEM courses by using a keyboard (or device that emulates a keyboard) alone.
WCAG 3. Understandable	<i>Instructional materials.</i> Definitions are provided for words, jargon, and idioms some students might not understand; all acronyms are spelled out when first used.
WCAG 4. Robust	<i>Forms.</i> Permission, lab reports, and other electronic forms can be completed using a wide range of devices, including screen readers and other ATs.

Information Resources and Technology. If your offerings use computers as information resources, ensure these systems employ accessible design, that staff members are aware of accessibility options, and systems are in place to make accommodations when requested.

- Do pictures in your publications and website include people with diverse characteristics with respect to race, gender, age, and disability?
- In key publications, do you include a statement about your commitment to access and procedures for requesting disability-related accommodations?
- Are all printed publications available (immediately or in a timely manner) in alternate formats?
- Do videos developed or used in the project have captions? Are they audio-described?
- Do you provide adequate work space for both left- and right-handed users?
- Are procedures in place for a timely response to requests for assistive technology?

Facilities and Offerings. Ensure that facilities, activities, materials, and equipment are physically accessible to and useable by all participants, and that all potential characteristics are addressed in safety considerations.

- Are all spaces welcoming, accessible, comfortable, and safe to a variety of abilities, racial and ethnic backgrounds, genders, and ages?
- Are aisles kept wide and clear of obstructions for the safety of users who have mobility or visual impairments?
- Are wheelchair-accessible and child-friendly restrooms with well-marked signs available in or near the facility?
- Is at least part of a service counter at a height accessible from a seated position?
- Are there ample high-contrast, large-print directional signs to and throughout the facility, including directions to accessible routes? When appropriate, are these signs marked in braille?

Staff. Make sure staff are prepared to work with all visitors and participants.

- Do staff members know how to respond to requests for disability-related accommodations, such as arranging for a sign language interpreter or providing a document in an alternative format?
- Are staff and contractors in specific assignment areas (e.g., web page development, video creation) knowledgeable about accessibility requirements and considerations?

Regardless of how many UDE practices are employed, although the need is minimized, reasonable accommodations may still be necessary to ensure full access and engagement to a particular student. For example, a student with a learning disability may require extra time on a test or assignment.

Conclusion

Practicing UDE instead of providing accommodations alone holds promise for making educational offerings more inclusive, both for students who disclose disabilities and request accommodations and for those with disabilities who do not, UDE practices benefits all students, including those with various learning styles and technological expertise, those whose native language is not English, those who are older than the average student, and those who are members of racial and ethnic minority groups. In summary UDE

- is applied proactively,
- makes a product or environment welcoming to all potential students,
- is useable by and accessible to people with a broad range of characteristics,
- can be implemented in incremental steps, and
- is offered in an inclusive setting.

The importance of increasing the diversity of persons entering the STEM pipeline has long been recognized, but only recently has it reached a degree of prominence that educational institutions and policy-makers are now mandating concerned efforts. The fields of science, technology, engineering and mathematics have long battled a problem of diversity. However, the focus of these efforts has changed in recent decades: initially, the focus was primarily confined to the underrepresentation of women in STEM, but increasingly this has broadened to include racial diversity (and the intersection of gender and race), socioeconomic class, neurodiverse persons (Wei et al., 2013), sexual orientation and gender identity, as well as persons with a disability.

Part of the reason for this expansion of focus has certainly been social changes in attitudes toward diversity. However, another factor has been the acute shortage of STEM-trained workers for an ever-growing variety of professions and the economic imperative to address this problem. A dire shortage of workers at all ability levels with STEM-proficiencies in Western countries has been temporarily catered for by importing overseas talents. Still, industry, educators, and policy-makers increasingly acknowledge the need to broaden the pool of new entrants into the STEM-pipeline. Not every child will grow up to become a scientist or engineer, but science and technology literacy is regarded by educators and economists alike as just as important for occupational success as reading and mathematics literacy. And we all benefit from a scientifically literate populous that can use critical reasoning and evidence as part of the basis for decision-making.

This presents a singular challenge for educators: how can we design an educational environment that cultivates and nurtures an interest in STEM for *all* students, and sees them carry this interest forward into their high school and college years. Young children are innately curious and passionate about science, but many lose this interest and see science as “not for people like me” in their high school and college years. Educators are very adept at teaching scientific concepts and principles, especially when adequately resourced and trained. But a higher standard is called for if we are to design an educational environment that delivers on the goal of inclusiveness. Meeting the challenge of a broadened scientific pipeline requires more than just rote learning and instruction: as educators, we need to inspire interest in STEM. Our goal should be that every student with the inclination sees the value in learning these skills, and that a career using those skills is something attainable and viable for someone like them.

With this aim in mind, we can glean some valuable lessons and perspectives from the social sciences (and psychology in particular) for cultivating a more inclusive STEM learning environment. In this article, we offer an overview of how educational psychology's perspectives can contribute to the design of equitable and inclusive STEM education. We also offer some evidence-based interventions that have been shown to improve STEM outcomes for underrepresented demographic groups (such as for women, for minorities, and for those from socially disadvantaged backgrounds).

Gender stereotypes about mathematics and science

One of the strongest barriers to students developing and maintaining an interest in STEM are gender stereotypes about STEM. Gender stereotypes that mathematics and sciences are inherently masculine domains of ability are widely held by students and adults alike, and are often due to the influences of old societal and patriarchal beliefs. However the intensity of such beliefs does vary across individuals. Gender stereotypes are of particular interest to educational researchers because of all social identity groups (race, social class, etc.), gender applies to the greatest number of students; hence there has been greater research into this than other social categories.

Such stereotypes might be expressed as explicitly held beliefs (“men are just better at maths”), or they may be more implicit attitudes (such as stronger associations between science and masculinity than for femininity). They also operate at many levels. Firstly, we see a direct impact of endorsement of gender stereotypes on students’ attitudes toward mathematics and science, with boys reporting more positive attitudes to studying STEM and girls reporting lower self-confidence and self-efficacy. Younger children show no such gender differences, however. These only tend to emerge during early high school years which is also a time of intensifying gender conformity pressures from peers and society (Martin and Ruble, 2010). Lest, the reader assumes this might reflect “innate” differences in patterns of interest between males and females, we find a curious pattern when we investigate STEM attitudes and abilities internationally. Reilly et al. (2017b) reported an analysis of the Trends in Mathematics and Science Survey (TIMSS), which assessed over a quarter of a million students across 45 different nations. For OECD countries (which are composed of primarily Western and developed nations) boys did indeed report greater interest in STEM while girls reported lower self-efficacy, but in many Middle-Eastern and Asian countries this pattern was reversed: with girls reporting greater interest, self-efficacy, and achieving higher mathematics and science achievement scores.

Secondly, both attitudes toward STEM and self-efficacy beliefs are important drivers of student subject selection in high school. While mathematics and science are generally required subjects at younger ages, in the later years of high school students are offered greater flexibility in their coursework and can voluntarily select some or all of their coursework. Students face an even greater range of choice on entering college and university: research shows that those who hold more positive attitudes and feel more confident about their abilities are more likely to choose STEM coursework than those who do not (Eccles, 2013). If we want to boost the number of women pursuing STEM careers, then inclusive education must start first in the younger years.

Thirdly, endorsement of gender stereotypes about ability affects how students approach STEM, and reduces motivation when students encounter difficult content. When “stuck” with a concept or technique they are trying to master, female students who have high endorsement of stereotypes are more likely to believe they lack the capability to solve it. Endorsement of gender stereotypes also affects student performance in examinations and standardized tests of achievement. This is particularly so when the outcome of the test has higher stakes (such as a college entry exam, or a final exam).

So where do gender stereotypes come from, and how strong are they? At an early age children are naturally inquisitive and that curiosity extends to the natural and physical sciences. Younger boys and girls are equally as interested in science. But as children age, they are influenced by parents and caregivers who control the types of toys and activities provided to their children, then by educators and teachers who are often their first introduction to the world of science. They are also influenced by various agents of socialization such as popular culture and media: when these representations of scientists and engineers are not representative of the general population and show a lack of diversity, it can internalize a message to very malleable young minds that science is “not for people like me”. Evidence suggests that these messages are acquired quite early, and that children begin to implicitly associate males with science and girls with language. In older adolescents the strength of these associations increases quickly, and there are measurable differences in attitudes toward STEM and self-confidence which increase further still into young adulthood. Let us look at some of the research on the strength of these gender-STEM stereotypes, and their effect on educational outcomes.

For younger students for whom filling out surveys is not ideal, one way of measuring these implicit gender stereotypes is the “Draw-A-Scientist” task, where children are asked to draw a picture of what a scientist looks like. As you might imagine, such drawings often reflect depictions of scientists in popular culture: scientists wearing glasses and dressed in lab coats, often middle-aged or older (Ferguson and Lezotte, 2020). It’s a task that allows a child to project their worldview without being led by the researcher or other adults present. Invariably, the scientists drawn are typically depicted as male (often Caucasian), even when girls are asked to draw them. A review of research conducted over the span of 5 decades in US children across K-12 found that 73% of all scientist drawings were male (Miller et al., 2018). While this attests to gender-STEM stereotypes’ pervasiveness, optimistically, the review found some signs of progress with time. There was a small decline in the absolute number of male drawings in more recent years. This was attributed to an increased representation of women in STEM and female scientists in popular culture, which has been referred to as the “Scully Effect”. A recent study of women engaged in STEM careers found that 63% reported that they were influenced by the portrayal of Dana Scully in the *X-Files* (Geena Davis Institute on Gender in Media, 2018), highlighting the importance of availability of female role models in STEM. While media and popular culture do have a role to play in shaping more positive attitudes toward STEM, this in isolation will be insufficient to address the underrepresentation of women in STEM fields.

Educational researchers can use surveys with older students to measure students’ endorsements of gender stereotyped beliefs (“such as males are better suited to mathematics and science”), as well as student interest in learning about mathematics and science or even student confidence. This varies across individuals and so can predict individual differences in educational outcomes. For example, higher endorsement of gender stereotypes about female ability is strongly predictive of lower female performance (Steele, 1998; Spencer et al., 1999). This is especially so for high-stakes standardized tests (such as the SAT-Mathematics test used for college entry in the United States) or end-of-semester examinations. Gender differences are also frequently observed by middle-school in STEM interest and self-confidence for US students and increase with additional years of schooling (Miller et al., 2006). This finding has also been replicated cross-culturally in international studies of mathematics and science attitudes (Reilly et al., 2017b).

Even for students who do not endorse explicit gender-STEM stereotypes, nonconscious implicit beliefs may also contribute to their relationship with STEM (such as lowering confidence). These cannot be measured directly on a survey but can be inferred indirectly through a variety of mechanisms. In older students, we can use a projective measure like the Implicit Association Test (IAT), which has been used to measure the strength of the gender stereotype (math = male). Nosek et al. (2002) found that

stronger implicit beliefs in this stereotype were correlated with more negative attitudes toward maths in women but more positive attitudes for men. A later study that investigated this effect cross-culturally found a moderate correlation between national gender-math stereotypes (using IAT data) and the magnitude of gender differences in maths achievement found in individual countries on PISA assessments (Nosek et al., 2009). Stronger math = male implicit associations lead to larger gender gaps in mathematics on standardized tests. So, there is good evidence that these stereotypes are widely endorsed (at least in Western countries), and that they impact mathematics and science achievement scores. However, in cultures/educational environments where these implicit beliefs are lower, girls actually score higher than boys in STEM (Guiso et al., 2008; Reilly, 2012). The take-home message of this research is that gender differences in educational outcomes are not immutable; the educational environment a student is raised in matters, especially in relation to the likelihood of maintaining their initial interest into STEM which can further develop into adulthood. With that in mind, we offer some suggestions firstly to parents and caregivers, and secondly for educators and policy-makers.

Parents and caregivers

Parents and caregivers can play a pivotal role in contributing to the acquisition of gender stereotypes, especially with younger children, as parents largely determine the activities and resources provided to the children in their care. This manifests through the toys, leisure pursuits and educational enrichment experiences made available to children as well as their parent-child interactions. At very young ages gender differences in socialization practices (and in particular, differential reinforcement of gender-appropriate toys and activities) were once thought only to influence gender differences in social behavior (Leaper and Gleason, 1996). However, play is an important part of child development and can be an enriching educational experience (Lillard, 2015).

Encouraging a broad repertoire of toy play is important, as play stimulates cognitive development: it gives the opportunity to practice important skills such as creativity, problem-solving, spatial reasoning, etc. Of relevance to early childhood education, many stereotypically masculine childrens' toys (construction blocks, cars and trucks, computer games, etc.) provide additional opportunities to practice and train visual-spatial skills (Reilly et al., 2017a), as well as to a lesser extent mechanical reasoning. These lay down a foundation for quantitative reasoning (mathematics and science skills), and have been recognized as giving children a critical headstart in STEM. For example, Lowrie et al. (2017) report that providing additional visual-spatial training improves elementary childrens' mathematics performance, and many educators now advocate incorporating an element of visual-spatial training in mathematics programs (Newcombe and Frick, 2010). Toy selection alone will not dictate a child's life outcomes, but it will contribute to their initial spatial abilities and readiness for STEM.

Parents are often regarded as a child's first teacher, because the lessons they will learn in the classroom rests on a foundation of informal learning experiences that begin at home. As most parents tend to buy gender-consistent toys for their children, many girls miss out on masculine educational toys that promote spatial development. Parents and caregivers can make targeted selections though that will provide additional spatial learning experiences at home for both boys and girls (Reilly et al., 2017a). This can start with geometric shape toys and build up to construction blocks such as Legos. Parents can also engage directly with the child in shared play, for example, by using spatial language during block play (Ferrara et al., 2011; Jirout and Newcombe, 2015), encouraging children to play games that promote spatial awareness, using jigsaws, maps and mazes to facilitate spatial perception and navigation skills.

Children are naturally inquisitive explorers of the world around them, or what the French educational psychologist Jean Piaget called "little scientists". They rapidly soak up an understanding of the world around them at these younger ages, including language, social behavior, and even rudimentary scientific principles (if I push the cup of water off the table, it will fall). While children remain curious their mind is flexible; but at later ages the range of possibilities for what a child will become narrows. Once children reach adolescence, they experience a sharp increase in gender conformity pressures from their peers (Ruble et al., 2006). Children begin to self-select their interests and leisure activities, and this extends to academic domains and tentative occupational aspirations (such as exploring a career in science or technology fields).

Yet parents are not completely without influence at these ages either, and parental beliefs about the importance of mathematics and science still make a strong contribution to girls' and boys' attitudes toward STEM (Jacobs and Bleeker, 2004). Where there is even a small spark of interest and curiosity, parents can exert a powerful contribution by providing access to science books, games, and science kits. However, parents tend to provide boys with more science-based educational toys and activities (Jones et al., 2000; Alexander et al., 2012), such as magnets, magnifying glasses, electrical circuits and fuses, mechanical kits, etc. than to girls. Yet, all of these though are equally appropriate for daughters, are low in cost, and can be a useful way of engaging in parent-child discussions about how science can be applied in everyday life. Also important are providing enrichment experiences like trips to science museums, planetariums and zoos, especially for children from lower socioeconomic backgrounds who might not get to experience these in school trips (Gerde et al., 2021). Sadly, daughters generally engage in far less science-based extra-curricular activities than sons (Catsambis, 1995). Drawing attention to this, and educating parents and caregivers about ways in which they can engage their daughters in such science-based extracurricular activities is important as, in addition to providing a nurturing educational experience, it sends a tacit endorsement to the adolescent child that these things matter, regardless of whether they are boys or girls. These informal learning experiences will reap dividends in the years ahead and expand the range of possibilities they can explore.

Teachers and educators

Mathematics and science literacy are already important cornerstones in a child's education, and both are taught as compulsory courses in most jurisdictions for a large part of a student's academic career. However, as mentioned earlier, in adolescence we see a sharp decline in girls' STEM self-confidence and attitudes (Catsambis, 1995; Reilly et al., 2017b). Some educators might genuinely wonder whether this reflects "innate" differences in aptitude between girls and boys for STEM, especially if they have read studies reporting higher male performance on standardized tests of mathematics and science (Hedges and Nowell, 1995). While males as a group do tend to score somewhat higher on maths and science tests than females, the differences in averages tend to be relatively small in magnitude (Reilly et al., 2015). They are only really consequential when you look at the gender ratio of high-achieving students, where males outnumber females by a factor of 2 or more in both domains (i.e., there are twice as many males as females at this level). This can lead to exaggerated impressions among educators and policy-makers of vast differences; gender ratios in high-achievers are significant but not immutable. Additionally, for science achievement scores they vary across content area: gender gaps are largest for physics and earth sciences, but girls score equally as high as do boys in biology and life sciences (Reilly et al., 2015). Indeed, when we look to young adult samples, females often outnumber males in many fields of science such as biology, psychology, and medicine. Thus there is no evidence of a lack of aptitude, and as highlighted earlier in international studies, there are many countries where girls score substantially higher than boys in both mathematics and science (Reilly, 2012; Reilly et al., 2017b).

Rather, gender differences in maths and science achievement on standardized tests (e.g., Hedges and Nowell, 1995) appear to be due to a tendency for girls to underperform on such tests due to the phenomenon known as *stereotype threat* (Steele, 1997). This is where awareness of gender stereotypes about STEM undermines confidence and increases test anxiety, especially on "high-stakes" tests like end-of-year tests or college/tertiary entrance exams—it can become a self-fulfilling prophecy that leads to underperformance. When girls are assessed by other means (such as written reports, essays) they tend to score on par with boys or somewhat higher. This is reflected in the gender gap in school grades, where girls as a group score significantly *higher* than boys in mathematics and science coursework (Voyer and Voyer, 2014). This is true even at more advanced levels in high school and college, where women typically earn STEM higher grades than men. There are, however, areas of science where this is the exception, such as chemistry and physics, and where numbers of women are also comparatively fewer.

Gender stereotypes about STEM can be particularly harmful, because they reduce interest and confidence in pursuing further maths and science coursework (Shapiro and Williams, 2012), and also undermine test performance when girls and women's abilities are assessed in exam situations. Reminding students that these stereotypes hold little validity, paradoxically, can be counter-productive as it reinforces awareness of the existence of those stereotypes (Liben and Coyle, 2014). Many well-intentioned efforts at improving gender diversity in STEM, such as the practice of single-sex schooling (Halpern et al., 2011), actually draw attention to gender distinctions and creates greater disparities in outcomes. Fortunately though, there are a number of evidence-based interventions that have been demonstrated to improve the performance of girls and women in STEM subjects, and can be offered broadly to all students rather than selectively targeting a select few. They are also relatively brief in terms of time, effort, and resources required to deliver them. In addition, they have the added benefit of improving STEM motivation and achievement more broadly (rather than just performance scores). This has importance for STEM course-selection and decision making by students. We review these later in the article under interventions, after addressing racial stereotyping and STEM.

Racial stereotypes about mathematics and science

Stereotypes about intellectual ability and race also present a problem for educators seeking to increase STEM diversity. Their origins are complex and multifaceted, but it was not so very long ago that some psychologists argued that white students were born smarter than African-American students, such as in Herrnstein and Murray (1994) widely repudiated book *"The Bell Curve"*. While the American Psychological Association devoted a considerable volume of research refuting such claims (e.g., Kincheloe et al., 1997), most readers will be familiar with the term "the Bell Curve" even if they are vague on the specific details of the book. Similar arguments were made decades earlier against desegregated education in the United States, but if we look more broadly, there are negative racial stereotypes about many ethnic and minority groups cross-culturally: such is the nature of prejudice. It is not confined to a single ethnic group.

When any minority group is systemically devalued and told that they are lesser, it sets the ground for reduced confidence about their intellectual abilities in those students. Steele and Aronson (1995) termed this phenomenon *stereotype threat*, and first applied it with African-American students. When there are negatively held stereotypes about intellectual abilities, especially when student ability is examined in high-stakes testing situations, this can lead to diminished academic performance. The psychological processes involved are multifaceted: but stereotype threat lowers memory recall (Régner et al., 2010), reduces problem-solving and the number of questions student attempt (Rivardo et al., 2011), and decreases student motivation and effort. In a meta-analytic review of more than one hundred studies investigating stereotype threat, Nguyen and Ryan (2008) found similar decreases in test performance with ethnic minorities as those found in studies investigating gender and stereotype threat. It is particularly problematic when students are "primed" to consider their group identity: such as filling out a pre-test demographic questionnaire that inquires about ethnicity (as is often used in state and national testing), or when there are cues in the testing environment (for example, being the only member of that minority group present relative to a room of white peers).

However, stereotype threat also affects students outside of testing situations: self-beliefs about academic abilities are pivotal to student motivation and persistence in the face of difficulties. It is well established that attitudinal factors and emotions play an important part in academic performance. Many students internalize negative beliefs about the racial/ethnic group to which they belong to, and may see academic achievement incompatible with that identity. This results in lower motivation, lower attendance, and higher dropout rates. Consequentially, it leads to a further narrowing of the pool of potential STEM candidates selecting mathematics and science coursework in high school and then again in college/university when considering a STEM major. [Steele \(1997\)](#) writes that there is a “universal connection between stigmatization and poor school achievement” (p. 623), and reports many examples cross-culturally. There are even examples of stereotype threat in caste-based minorities of the same race, with similar-sized educational gaps to that found between African-American and Caucasian students, so the effect seems to apply to any stigmatized social group rather than reflecting any actual differences in aptitude.

At the heart of these stereotype threats, effects on student attitude and performance is the internalization of the message “I don’t belong here ... STEM isn’t for people like *me*”. Belonging is a fundamental human need ([Baumeister and Leary, 1995](#)), and feeling like you belong in an academic environment is critical for academic success. However, this is harder for underrepresented racial minority (URM) students to attain in a student body predominantly composed of white students and where they may lack established social networks such as in the transition to high school or college. [Walton and Cohen \(2007\)](#) examined students’ sense of belonging in undergraduate STEM students, finding that URM students rate their sense of belonging significantly lower than their peers. Challenging these student perceptions can be difficult, because targeted interventions that act on a specific ethnic/racial group can often highlight the salience of race (just as we see the same with targeting only female students mentioned earlier). One intervention though that shows promise directly targets a student’s sense of belonging, and acknowledges the difficulties URM students may be facing. [Walton and Cohen \(2007; Study 2\)](#) found that a 1 h information session completed as part of their orientation substantially reduced the racial achievement gap in STEM students. Students were presented with information on how common it is for students to feel out of place and like they don’t belong, regardless of race, including illustrative quotations from past students about how this improves over time and gets easier. It also presented the results of a study showing graphs of how these fears were common across racial and gender groups. This was delivered to *all* students in the study regardless of demographic category so as not to make group identity salient. The students were then tracked over the course of their first semester of study. While there was no substantive difference for white students, its effect on minority students was remarkable. Relative to controls, URM students receiving the intervention earned substantially higher GPAs ([Walton and Cohen, 2007](#)), and this effect persisted throughout the course of their degree ([Walton and Cohen, 2011](#)). Such interventions are brief and low-cost, so might be implemented in introductory STEM courses at colleges and universities. But they might equally be considered earlier in high school at the beginning of the school year.

Up until this point, we have focused primarily on attitudinal factors within students themselves. However, it would be remiss not also to consider the impact of contextual factors, which includes the attitudes of STEM teachers themselves. Many educators will be aware of the classic “*Pygmalion in the classroom*” study that showed just how teacher beliefs about their students’ potential translate into measurable differences in learning outcomes ([Rosenthal and Jacobson, 1968](#)). Even in the absence of overt racism, there is the potential for situational cues from STEM instructors to reinforce racial stereotypes. There is some evidence to suggest that these Pygmalion effects are stronger for URM students, and that URM students report their instructors as having lower expectations for them ([McKown and Weinstein, 2008](#)). It also illustrates how even educators who hold quite egalitarian racial attitudes might still reflect the prevailing implicit beliefs of their culture ([Greenwald et al., 2002](#)), through the burden of low expectations. Conversely, educators who can see the potential in their students (even when those students cannot yet see it themselves) can be transformational in inspiring STEM potential to blossom ([Rochmes, 2018](#)).

A comprehensive longitudinal study by [Canning et al. \(2019\)](#) investigated whether this might be the case for STEM courses, given the afore-mentioned implicit attitudes of scientists being white males. They examined racial gaps in STEM course grades across more than 150 different instructors, numerous STEM disciplines, and a sample of over 15,000 students. They also surveyed instructor beliefs about the malleability of intelligence: whether intelligence is fixed at birth, or whether intelligence can grow with effortful learning and practice. They found that racial achievement gaps were substantially larger when taught by instructors who held a “fixed” mindset compared to those instructors with a growth mindset. This was observed even after controlling for other influential demographic factors like gender, socioeconomic status, first-in-family to attend college, etc. There is also evidence that teaching students about a “growth mindset” may help change how they see themselves and their approach to learning STEM, especially for students entering high school ([Yeager et al., 2016](#)). Many students believe their ability to be fixed: if they can’t understand a particular task like algebra or chemistry now, then they won’t be able to understand it in the future. When this is reinforced by implicit cultural attitudes about intelligence and race, it can affirm a “fixed mindset” and discourage further practice. The argument has even been made that this should be taught to all students, but [Yeager and Dweck \(2020\)](#) note that it is particularly effective in cases where students (due to stereotyping) have low expectations of themselves.

If we want to broaden the diversity of STEM graduates to create a more inclusive STEM workforce, then we must work hard to capture their natural curiosity about STEM in early education, and then carefully nurture and safeguard it throughout their schooling career ([Herrera and Hurtado, 2011](#)). Studies generally find that URM students hold the same level of initial interest and enthusiasm for STEM as their white peers across middle and high school ([DeWitt et al., 2011](#)), as well as similar levels of parental encouragement and aspirations toward STEM. However, they also have less access to science enrichment activities outside of the school setting, and may lack the financial resources for technology that other children take for granted ([Archer et al., 2012](#)). It is here that educators and policy-makers can make a critical difference by providing funding and support for additional STEM enrichment experiences and technology access for the students in their care. [Archer et al. \(2012\)](#) identified ages 10–14 as a “critical

period” for URM students and STEM, during which additional science experiences and resources can help nurture their interests and talents. However, we would caution against interventions targeted at specific ethnic groups because of the unintended consequences of labeling; rather, students from any demographic group would benefit from increased technology access and STEM enrichment, such that there is a flow-on effect with increased ethnic representation.

Another factor identified as contributing to underrepresentation in STEM is that, despite equivalent interest in STEM, URM students tend to enroll in less challenging math and science coursework (Xie et al., 2015). They are also more likely to be placed in remedial and low-track academic streams. Undoubtedly, this has a profound impact on students’ academic self-image and motivation and leaves them unprepared to undertake further STEM coursework in college. Educational support and intervention prior to the age of voluntary course selection may be critical in building STEM aptitude and confidence, as well as psychoeducational interventions like values affirmation (see below).

Educational interventions to reduce gender/racial gaps

Frontline teachers and educators have the very best of intentions in promoting an inclusive learning environment but have only finite time, energy, and resources to do so. Educational fads come and go, with mixed results that do not always translate to improved learning outcomes (Dinham, 2017). Therefore, it is imperative that adopted educational interventions and strategies have a strong track record of proven results. This is referred to in psychology as evidence-based interventions. When conducting research in this area, educational psychologists largely write for a psychologically trained audience who can understand esoteric statistics and then publish in psychology journals hidden behind paywalls to which only universities usually have access. This disseminates information within the field of psychology well, but we often do a very poor job then of translating that body of literature into an accessible format for educators and policy-makers. The end-result means that some very promising educational interventions have been developed but never reach the coalface of teaching in schools. We seek to remedy this here today.

A number of educational interventions have been proposed for addressing racial, gender, and socioeconomic gaps in educational outcomes for STEM. Many though lack a firm and reliable evidence base, have relatively weak effects, or require considerable investment in resources or classroom time. However, two particular educational interventions that have withstood the crucible of scientific scrutiny, have been widely applied across a range of STEM disciplines (generalizing to all areas of mathematics and science), and are both low in cost and their demands on classroom time. Additionally, these interventions’ effects are so strong that they translate to enduring effects rather than temporary, transient effects. Both spatial training and values affirmation can be applied with any age group, and with limited resources. While we would highly recommend that policy-makers consider adopting them, their potency and low-cost mean that STEM educators could easily implement them in their own classroom settings.

Spatial training

Visual-spatial skills are the ability to perceive and understand spatial relationships, to visualize spatial stimuli such as objects, and to mentally manipulate or transform them in some way (such as rotating an object to imagine what it might look like from a different angle or perspective (Reilly et al., 2017a)). These skills are used quite heavily in certain areas of mathematics (like geometry and trigonometry), as well as more applied fields of science such as physics and chemistry. For several decades, evidence has been growing that visual-spatial reasoning lays down a foundation for quantitative reasoning (a collective term for mathematics and science thinking). Though the exact reasons for this are still unclear, more than 50 years of educational research demonstrates the relationship between spatial ability and science achievement scores is quite strong (Wai et al., 2009). Furthermore, it applies broadly across many different STEM disciplines including chemistry, physics, engineering, and computer science (Uttal and Cohen, 2012).

Typically, males have significantly higher visual-spatial ability, and the size of this gender gap is quite substantial. The reasons for this are complex and a matter of some debate in psychology (for a review see Halpern, 2011), but there is strong evidence that the amount of spatially-oriented play and leisure activities students participate in is positively correlated with visual-spatial ability (Doyle et al., 2012). As with other academic skills like reading, visual-spatial skills require considerable practice to develop fully. For most children and even many adults, visual-spatial skills are underdeveloped and require further environmental input in the form of spatial learning experiences. However, the gender gap in visual-spatial ability is substantial, and spatial training offers the potential to reduce this. Fortunately, there is a way to “shortcut” the many hundreds of hours such activities would normally require and boost visual-spatial reasoning considerably. Spatial reasoning skills are highly malleable and can be improved with training (for a review see Uttal et al., 2013). In a meta-analytic review of over two hundred studies, the average effect of training was moderately large ($d = 0.47$). While early education for spatial learning is desirable (Newcombe and Frick, 2010), students can benefit from spatial training at any age with the review reporting similarly sized effects in adolescent and adult samples alike. As spatial reasoning scaffolds later quantitative reasoning, many educators advocate providing additional spatial training. Again, we would caution though that this should be offered to all students, rather than selectively targeting females in isolation. Students from lower socioeconomic backgrounds, for example, also tend to have less developed spatial reasoning (Levine et al., 2005), and this may help level the playing field. Interventions can take the form of specific lessons teaching particular spatial skills, practicing spatial tasks like mental rotation and then receiving feedback on their performance, or even video games that have students perform spatial reasoning tasks. All offer fairly substantial improvements to visual-spatial reasoning skills (Uttal et al., 2013).

Educators might legitimately wonder whether it is worth allocating time and resources to spatial training for their students, and whether this actually translates to improved STEM outcomes. By way of example, we present two studies investigating the flow-on effect for mathematics achievement: one for younger children, and one for high school-aged students. A recent study by [Mix et al. \(2020\)](#) investigated whether providing several very brief, 30 min spatial training and practice sessions over the course of a week would boost elementary students' spatial and mathematics performance. The study recruited students from first and sixth grade, and the interventions were administered using iPad devices with which children were already familiar. What is notable about this particular study is the wide array of tasks they employed to measure mathematical ability (to test whether spatial training would transfer to all or just certain types of mathematics skills). These included number line estimation, arithmetic calculations without calculators, word problems, and basic algebra. Students showed a significant improvement in their mathematical performance for all tasks compared to a control group that did not receive spatial training. In another high-profile study, [Miller and Halpern \(2013\)](#) report the results of a longitudinal study into the benefits of offering spatial training in a group of STEM undergraduates. After experiencing six 2 h spatial training sessions, the gender gap in visual-spatial ability narrowed considerably relative to a control group that did not receive the training. Students were then followed over time, and their test scores in a college physics course were examined. Students who received spatial training scored significantly higher in their physics mid-terms, as well as the more demanding final exam. Students also reported greater self-confidence in their physics abilities relative to controls. Additionally, students who were enrolled in biology courses also went on to earn high grades than the control group. Similar results were reported by [Stieff et al. \(2014\)](#) with chemistry grades. These and other studies illustrate the benefits of spatial training for all students, and that such training translates to both improved mathematics and science achievement ([Sorby et al., 2018](#)).

Values affirmation

Gender and racial stereotypes about STEM prove particularly problematic for inclusive education. Even when taught by passionate educators who value the worth and dignity of every student, these stereotypes are still foremost in the minds of the students they teach: students are keenly aware that their identity (as a minority) differs from that of the typical STEM scholar. Thus, diversity training and affirmative action initiatives may be moot without also considering the social-psychological processes that affect student learning. As mentioned previously, attempts to "challenge" these stereotype beliefs can be problematic: even when explicit beliefs are refuted by counterexamples (such as the previously mentioned higher female grades in many STEM subjects), the implicit beliefs remain resistant to change. Indeed, they may even increase in intensity through the highlighting of race or gender identity. Rather, we need to inoculate students against these stereotypes and increase their resilience in the face of them.

Values affirmation is a brief yet effective intervention shown to deliver considerable increases in STEM achievement and motivation. More importantly, they can plausibly be administered to all students rather than singling out specific subgroups. After all, many students at one time or another feel like they don't belong, that the degree or courses they've chosen are not for "people like them", or what is commonly referred to as imposter syndrome. Though it may affect any type of student, women and ethnic minorities are greatly overrepresented in studies investigating the prevalence of these doubts ([Bravata et al., 2019](#)). While gender and racial subgroups are the most widely researched in this area, values affirmation is also equally applicable to other categories: students coming from a low socioeconomic status background, first-in-family to undertake college/tertiary studies, LGBTQIA, etc. As it targets motivation and strengthens resolve, it offers benefits for all students who receive the intervention.

The active ingredient in a values affirmation intervention is a reflective writing activity, typically set administered in class-time so that students give it serious consideration. [Miyake et al. \(2010\)](#) had students taking an introductory physics course at college complete a 15 min writing exercise in the first week of class. Students were told that communication is an important skill in a STEM degree and that rather than writing about physics (which they've yet to learn), they would instead practice writing about something they were already familiar with: themselves. In the values affirmation condition, they were asked to identify their most important personal values from a pre-defined list (such as inherent curiosity, their relationships with family and friends, being part of the community, their religious or spiritual values), and in a series of prompts were then asked to write why these were important to them. These served to remind the students of why they were here, and how they hoped to use the skills they were learning to have an impact. The mere act of writing an essay about their personal values appears to lead to greater tolerance for stress in the face of adversity and reaffirms people's individual worth ([Cohen and Sherman, 2014](#)). A control group completed a neutral writing task instead. Such exercises have been found to reduce racial achievement gaps in middle-school students ([Cohen et al., 2006](#)), but [Miyake et al. \(2010\)](#) were the first to examine its effect in reducing the gender gap in college students taking introductory STEM courses. Typically, the "washout" rate of these introductory courses is high, and they are sometimes referred to by educators as "weed-out classes" ([Chawla, 2020](#)). However, they can also be a bottleneck that greatly diminishes the diversity of students studying STEM: so even a very small impact of a values affirmation intervention could be greatly beneficial here. Student progress was then followed by the researchers over the course of the semester, and their final grades examined. The gender gap was eliminated entirely in those receiving the intervention, and the modal (most frequently occurring) grade for the values affirmation group raised from a C to a B. Improvements were highest though for women who endorsed had previously endorsed the belief that men are better suited to physics.

Given the simplicity of values affirmation exercises and the impressive effect on grades, there might be some natural skepticism among educators. After all, sometimes, psychological interventions can be due to sampling error (if the randomly selected control group was slightly lower in initial ability than the treatment group), and so may not be repeatable. Educational researchers set out to

replicate the values affirmation study with their own student samples. A replication study by [Kost-Smith et al. \(2012\)](#) found a similarly large effect on mid-term and physics finals at the University of Colorado, and as they had access to their student's SAT scores, the researchers were able to control for this statistically to ensure that the groups were equivalent at the outset. Other researchers have investigated whether values affirmation interventions might benefit other demographic groups, such as students coming from a lower socioeconomic background or belonging to an URM in STEM. [Harackiewicz et al. \(2016\)](#) applied a values affirmation intervention to four semesters of first-year biology students, finding that it reduced the achievement gap in students who were the first-in-their family to attend college and as well as URM students by about half a GPA point. Offering such interventions in introductory STEM courses might well make for a more inclusive, and more diverse student composition, as it buffers students against adversity and feeling like they don't belong. While it has been studied most heavily on boosting STEM achievement in female students and underrepresented ethnic minority students, it might well offer benefits for other demographic categories such as different sexual identities or orientations, students with a disability, etc.

Encouraging diversity and broadening the pool of students taking STEM coursework

Throughout this article, we have presented the perspectives of educational psychology research in the hope that this information will be of use to parents, educators, and policy-makers: all of whom have important roles to play in reaching a more diverse and inclusive STEM-trained society. We have focused most specifically on improving gender and racial diversity in STEM, and to a lesser degree socioeconomic status. Together these three areas have received the lion's share of attention in the research literature, and collectively represent the largest demographic groups. However, it would be remiss not to also briefly mention other subgroups, such as the underrepresentation of students with a disability ([Weinstein et al., 1987](#); [Xie et al., 2015](#)) and sexual minorities ([Sansone and Carpenter, 2020](#)) who are also less likely to participate in STEM. But imagine what a different world it would be today without the past contributions of scientists like Stephen Hawking (in the case of physical disabilities) or mathematician and father of artificial intelligence Alan Turing (who was jailed for homosexuality, but only after completing his work on breaking the Enigma encryption used by the Germans in WW2). Inclusive STEM education must make all willing students welcome: that requires a culture of support and respect that does not discount people because of group identity. But it must also consider the possibility that those who may differ from the prototypical image of a scientist may not yet recognize their own strengths and aptitudes, and may need encouragement and mentoring by parents and educators.

There are some scientific challenges that can eventually be solved by devoting sufficient computational or labor-force to it, albeit with some inefficiencies and diminishing returns. But there are other, more herculean, scientific problems that have remained intractable for many years. They require that spark of ingenuity, that leap of inspiration, that just might lie in the hands and heads of the next generation of students. So, with this in mind, there is one other category of student that we would urge parents and educators to consider encouraging and supporting in their STEM journey if indeed that's where their talents and interests lie. That would be the neurodiverse student who may take a particular interest in mathematics, science or technology.

For those unfamiliar with the term, neurodiversity is a broad catchall for individuals on the autism spectrum,¹ but also includes many other conditions such as attention-deficit disorder, dyslexia, dyscalculia, which educators frequently encounter. There is some evidence to suggest, for example, that autistic individuals are more likely than the general population to hold an interest in either mathematics or science, and as such, are highly prevalent in these fields. In a nationally representative sample of autistic students attending college, [Wei et al. \(2013\)](#) found that autistic individuals were significantly more likely to have chosen a STEM major than other disciplines, while [Baron-Cohen et al. \(2001\)](#) report that scientists score higher on the Autistic-Spectrum Quotient (a measure of autistic traits) than non-scientists. Similarly, [Shmulsky et al. \(2019\)](#) report in a survey of STEM educators that there is a high prevalence of autistic students among higher achievers, and that they often bring fresh and innovative perspectives. As they have found, the most common features in autistic individuals studying in STEM fields are creativity, abstract-thinking and critical reasoning.

These are exactly the attributes we need in the STEM workforce, and we would urge educators and career guidance counselors not to overlook the possibility that neurodiverse students have to offer. Additionally, there's quite a high prevalence of students with various levels of attention-deficit disorder, reading impairments, or even dyscalculia among college students ([DuPaul et al., 2009](#); [Nelson and Gregg, 2012](#)). Educational accommodations for college and university students are available, but our personal experiences in teaching said students is that they are often unaware these supports exist and are already high functioning independently. If they do not see it as a barrier to pursuing an education in STEM, then we'd urge educators at every stage (from early education to elementary and middle school, through to high school and beyond) to give such students the same attention, encouragement and mentoring they would any other and not discount them prematurely.

So, we would encourage parents, educators, and even students themselves to consider all demographic groups as potential STEM achievers, regardless of social class, or group identity. The many scientific, technological and engineering challenges facing the world today and in future decades will be best served by a diverse and inclusive STEM workforce bringing to bear their differing experiences and perspectives. While we have made great progress toward increasing STEM diversity, we have so very far yet to go.

¹In order to show respect for the diverse communities we write about in this article, we use the terms *autism spectrum* and *autistic*, rather than *autism spectrum disorder* as specified in the DSM-5 diagnostic manual. This is to ensure we respect preferences of the autism community and autistic advocates.

Background

In the contemporary world, since science and technology have become a foundation of overall industries, careers requiring STEM (science, technology, engineering, and mathematic) skills are becoming more abundant at the job markets (National Science Foundation, 2014). Given that the single most important factor that students consider in developing career aspirations is chances or size of future job markets, it was expected to have enough students who want to pursue STEM studies at college as the market grows (Sithole et al., 2017). However, ironically, in the last two decades, students, especially in secondary education have indicated a negative trend in their interest in science and STEM careers especially in many western developed countries (Kang et al., 2019a; OECD, 2016), and consequently, there is a lack of college students who pursue STEM majors such as physics, engineering, or computer science requiring advanced mathematic skills (Giffi et al., 2015). Interestingly, these are the majors that are dominated by males at higher education for the past twenty years (Diekman et al., 2010; National Science Foundation, 2014; Stoet and Geary, 2018). Thus, this lack of STEM workforce problem might be addressed with gender perspectives to improve the situation since this lack of women's participation slows national economic growth as well as gender equity (National Academy of Sciences et al., 2007).

So, why do female students try to avoid learning science and mathematical studies compared to males at school? In the past, some researchers suggested biological differences between female and male especially in brain structure; that is, males naturally have better mathematical abilities than females that make differences in career choices between gender in STEM fields (Ceci et al., 2009, 2014). However, recent national and international large-scale studies have indicated negligible gender differences in mathematics and science achievements; moreover, some countries, like Finland, indicate that girls are continuing to outperform boys in science (OECD, 2016). Indeed, girls are not only performing better in science but also other school subjects than boys at school (Stoet and Geary, 2018; Ullah and Ullah, 2019). Interestingly, however, girls have constantly indicated lower interest and self-efficacy in science and mathematics than boys (OECD, 2016; Stoet and Geary, 2018) that may impede them to pursue science careers. This seems to defy logic, given that interest and self-efficacy in science are known as strong indicators of achievement (Kang and Keinonen, 2017). Thus, there must be more complex interrelationships between achievement, interest, and self-efficacy in explaining gender differences in STEM career aspirations. Accordingly, in this review paper, we will discuss gender differences in abilities, interest, and self-efficacy, and how these constructs are interconnected with STEM career aspirations differently by gender based on recently published articles.

Another important factor related to the gender issue in STEM seems to lie in student perceptions of science careers (Archer et al., 2013) and their lifestyle preferences (Kang et al., 2019a). According to Archer et al. (2014) for instance, students still perceived the image of scientists as male, white, nerdy or geeky that are not favorable for females. Besides, student (mis)perceptions of lifestyle or working environment of STEM careers have indicated a negative effect on female students' pursuit of STEM careers. While females put much value on communal goals in their work and life than males, science was perceived as being uncommunal (Boucher et al., 2017); females in many cultures have more responsibilities in taking care of children so they prefer to work with high flexibility, while STEM careers are known to be spending much more time to work than other fields (Ferriman et al., 2009; Frome et al., 2006). Therefore, how to perceive such careers might affect students' study and career decision making processes stronger than the reality of the careers and the actual working environment, and these perceptions are highly related to cultural environments. Therefore, we will also discuss how these perceptions have affected students' STEM career choices and how they are interrelated with cultural aspects.

Relationships between abilities, interest, self-efficacy and STEM aspirations

In the last few decades, it has been reported that females did not select STEM-related studies and careers due to their lack of biological abilities in science and mathematics compared to males (Ceci et al., 2009). However, recent international large-scale studies such as Program for International Student Assessment (PISA) have reported that while female students indicated higher performance in science in many participating countries, males indicated higher self-efficacy and they pursue STEM careers more than females (OECD, 2016). Of course, within the same gender group, the one indicating a higher achievement in science presents higher

STEM aspiration, but when comparing different gender groups, this pattern is not revealed. Concerning this, [Stoet and Geary \(2018\)](#) found an interesting pattern from the PISA 2015 dataset that females indicated higher scores in Science and Reading than males, but the reading score gap between gender was higher than the science score gap. That is, although females outperform in science over boys, their strength in reading is relatively greater than in science. Accordingly, these relative personal abilities in other subjects may lead females to choose diverse options “in which they can gain the most benefit from their relative strength in reading” (p. 588). On the other hand, Science was usually the top strength of males comparing to other subjects and this led males to indicate higher self-efficacy than females. In the end, high abilities in other areas such as reading and low self-efficacy in science draw females away from STEM careers. Interestingly, this pattern is more and clearly presented in high gender-equal nations such as northern European countries like Finland (p. 591). Similarly, [Wang et al. \(2013\)](#) reported that, although high mathematical skills are a precursor of STEM career aspiration in general, individuals who had both high verbal and math skills are less likely to pursue STEM occupations than those who possessed only high math skills. Interestingly, there are more females in the group of high verbal and math skills but more males in the group of high math skills. However, males indicated higher self-concept in their math abilities than females and this self-concept in math influenced on STEM career choices for both females and males. Again, this study confirms that, females who have higher abilities in diverse subjects than males are likely to have more career options to choose and to possess lower self-efficacy in mathematics so that females may gravitate away more from STEM careers than males.

In addition, [Cardador et al. \(2020\)](#) argued that not only relative abilities but also relative or surplus interests in other areas may take women away from STEM careers. In their surplus model, they controlled abilities and examined the effect of two coexisting interests in STEM and other surplus areas such as Enterprising or Artistic interests. Then, they compared males and females to investigate whether these surplus interests moderated the relationships between gender and STEM interest. According to the results, females with high STEM interest chose disproportionately lower STEM careers as their surplus interest in other areas increased. Therefore, they concluded that “female adolescents with strong STEM-related interest should be less likely to pursue STEM careers when they also have strong interests in other areas, due to wider career options” (p. 1).

Surprisingly, a similar pattern was recently reported in Finland from very young children aged 8 to 10. [Oppermann et al. \(2021\)](#) conducted a longitudinal study for second and third graders in primary school concerning their interest and self-efficacy (as motivation) in science, mathematics, and Finnish language. According to the results, first, they found three motivational profiles as high motivation for all subjects, high motivation only in math, and low motivation for all subjects groups. Second, the high math motivation group indicated the highest STEM aspirations than the other two groups, and boys were overrepresented in this group. In addition, the stability of boys in the math motivation group was higher than girls between second to third grades, and “odds of students who remained in the math-motivated profile from second to third grade to name STEM aspirations were six times greater than for students who remained in the high motivation (for all subjects) profile” (p. 10). Thus, the results show that STEM careers are mostly aspired by students with single motivation in mathematics compared to students with multiple or surplus motivations probably due to the increased options for the latter group, and this pattern is already visible from elementary school students.

On the other hands, some studies show that science interest and self-efficacy affect career aspiration differently by gender. [Kang et al. \(2019b\)](#) conducted a longitudinal study between age 13 and 16 in Finland concerning causal effects of interest and self-efficacy on STEM career aspirations. According to the results, first, they found that self-concept stayed stably during the 3 years while interest increased significantly for both female and male students. Second, while both interest and self-efficacy influenced male student STEM aspirations, only interest was revealed as a strong predictor of the female student STEM aspirations while the effect of self-efficacy was negligible for females. Also, [Sax et al. \(2015\)](#) found that “the salience of MSC (math self-concept) in predicting STEM major selection has generally become weaker over time for women (but not for men). Ultimately, this suggests that women’s lower math confidence has become a less powerful explanation for their underrepresentation in STEM fields” (p. 813). Overall, these studies show that there are different effects of interest and self-efficacy on STEM aspirations by gender, and females may consider their internal satisfaction more than their perceived abilities when they aspire STEM careers.

Effect of perceived characteristics of STEM careers and lifestyle preferences on a career decision

Perceived characteristics of STEM careers including images of science and scientists and individual lifestyle preferences such as family-oriented are known to be strong predictors of STEM aspirations ([Archer et al., 2014](#); [Ferriman et al., 2009](#); [Kang et al., 2019a](#)). As adolescent’s career aspirations are influenced by contextual factors through socialization processes, the perceptions of specific careers and preferred lifestyle are also affected and formed by socio-cultural environments that individuals are surrounded ([McDaniel, 2016](#)). During the last decades, from career counseling and science education studies, it has been widely studied about the preferred working environment of men and women, and much research reported that while men prefer more things-oriented works such as making and developing a new product, women look for more people-oriented occupations aiming for communal goals such as helping, working and spending time with other people ([Diekman et al., 2011](#)). Also another study showed that men are more career-oriented and agentic, while women seem to be more holistic and attendant to family and the social well-being ([Ferriman et al., 2009](#)). [Diekman et al. \(2017\)](#) explain it under a goal congruity framework describing that a key factor affecting individual career pathways is the perceived alignment between social roles and career goals. However, since STEM careers have been (mis)perceived as being antithetical to communal goals and more things-oriented occupations, especially engineering and technology disciplines, women were likely to be deterred from STEM careers as well as communally-oriented men ([Diekman et al., 2010](#)) although STEM careers hold the key to supporting people and society in reality. Interestingly, college student choices of

not only STEM (Fuesting et al., 2017), but also Non-STEM majors are influenced by the perception of each major whether they are helpful to people (Ganley et al., 2018).

The development of these perceptions and preferences of STEM careers seems like to start from very early ages and continuously proceed through adolescents. According to Bian et al. (2017), children at ages 6 and 7 already indicated gender stereotypes such as *boys are smarter than girls*; these prejudices may influence children's interest in certain fields like STEM that are also perceived as the fields for smart people; consequently, it is "likely to narrow the range of careers they (girls) will one day contemplate" (p. 391). However, until at age 8, children draw roughly the same number of male and female scientists (Miller et al., 2018) although boys indicated higher self-concept and intrinsic value in mathematics than girls in this period (Oppermann et al., 2021). Thus, while these young children think that science and mathematics are more for boys, they do not have any bias on scientists' gender yet. Then, children begin to draw more male scientists during upper primary and lower secondary school, and by the time when they are in upper secondary school, the proportion of male scientists in their drawing becomes four times more than female scientists (Miller et al., 2018). Thus, it is plausible to assume that the earlier image of science for boys is transferred to the image of a scientist as males in the later phase. According to Archer and her colleagues, however, young students' views of scientist improved from 10 to 14 (Archer et al., 2013). That is, when they were in primary school, students perceived science as being hard and scientists as geeks, so girls did not want to have such careers that were unfavorable for them. However, when they got into the secondary school, students expressed much more positive views of scientists and their works for society. In addition, their follow-up study showed that student STEM career aspirations established at age 10 were fairly being stable until age 18 (Archer et al., 2020). Thus, they concluded that "low levels of science aspirations were not a consequence of ... the effect of negative views about scientists" (p. 5). That is, student STEM aspirations were being stable from age 10 to 18 while student views of scientists had improved; thus, there may be no significant relationships between aspirations and perceptions of STEM careers. However, what they have missed is that the views of scientists were already affected students' interest in STEM careers especially for young girls at age 10 as they perceived scientists as being "male", "smart", or "odd" which decreased their aspirations in STEM fields significantly at that moment. Since this low STEM aspiration at age 10 continued until they became age 18, it is hard to say that the negative views about scientists do not influence on STEM aspirations in future. Rather, it is better to conclude that the negative views (or prejudices) about scientists at an early age have a strong impact on their later STEM aspirations at age 18.

Perceived working environments is one of the critical factors affecting career decision and it is related to individual lifestyle preferences and goals such as having and caring children which is one of the most important concerns for women. Traditionally, in many cultures, girls have been expected to be a primary caregiver of their children and family in future, so it has affected girls to consider such careers perceived to be more flexible for the sake of family (Frome et al., 2006) and it leads them to be interested in a greater number of different careers than boys (Mendez and Crawford, 2002). In practice, unfortunately, since many STEM-related careers (usually male-dominated) do not (or are perceived not to) offer flexible working environments, girls and women who accept their role as the primary caretaker are not able to follow their career plans despite their abilities in STEM fields (Frome et al., 2006). According to Weisgram and Diekmann (2017), STEM occupations were perceived as incongruity with family goals, and this perception emerged more strongly with older age cohort. Also, Ferriman et al. (2009) reported that women in STEM desired more flexible, weekends free, and less working hours when they became parents while men did not show any significant changes before and after having children. Thus, as stated by Frome et al. (2006), desire for a family-flexible occupation and high time demands of occupation become strong predictors of women changing their aspirations out of STEM fields. Overall, this traditional gendered role particularly women as a primary caregiver of children may be related negatively to the perceptions (or realities) of STEM working environment so that there are few numbers of women in STEM occupations.

In a recent study, the similar pattern was also revealed from young students aged 13 in Finland as careers perceived as giving enough time for family indicated a significant relationship with their STEM interest for both girls and boys (Kang et al., 2019a). However, the results were surprising since girls' personal time orientation was positively connected to STEM aspirations. That is, Finnish girls perceived STEM careers as flexible in terms of time management so that they thought that they can combine STEM careers with family responsibilities. Given that Finland is well known as its high gender equal society and flexible working environments, this gives a good insight as to how the national and cultural environments can affect student STEM interest and future career perspectives. However, although expecting to work in STEM fields during adolescence plays a key role to lead them to the eventual STEM career (Legewie and DiPrete, 2014), since young adolescents' STEM aspirations are continuously changing during and after the secondary school as well as college, this positive perception of STEM careers as family friendly should be followed up carefully in Finland. For instance, Frome et al. (2006) argued that girls at 12th grade who were interested in STEM fields, decided to stop pursuing STEM careers at age 25 if they perceived the STEM environments as not family friendly while studying at college.

Also, at college, one of the raised gender issues in STEM seems to line in, so called, masculine and chilly climate "as fields with larger gender differences tend to be the ones that are perceived as more stereotypically masculine" (Ganley et al., 2018, p. 457) such as engineering or computer science. One major result or effect of this misperceived or practiced masculine culture at college is to attain and retain unqualified men over more qualified-women since "low-achieving men are both retained in and attracted to these fields during college" more than high-achieving women (Cimpian et al., 2020, p. 1319). Ganley et al. (2018) thus argued that the lower proportions of women in STEM fields are attributed to college student perceptions of such majors as being unwelcoming to women. They also showed that if women perceived such college majors do not discriminate against them, they may "choose majors that lead to higher paying careers" such as STEM (p. 478). Bloodhart et al. (2020) also showed that while women outperformed men in physical and life science at college, their abilities were undervalued by peers.

This “chilly climate” toward women in STEM fields has been well documented since the 1980s (Britton, 2017), but recent studies show that the situation has been improving gradually in both academy and society. In order to examine whether chilly climate affects women’s decision on switching majors from male-dominated fields, Riegle-Crumb et al. (2016) investigated whether women who entered male-dominated fields such as computer science or engineering were more likely to change their majors compared to women who were in other college majors. Surprisingly, according to the results, there were no differences between women of male-dominated fields and other general fields in terms of the switching decision. Specifically, 59% of women in the male-dominated fields stayed in their majors compared to 51% of women in other majors. Thus, they concluded that women’s decision to switch was not affected by the number of males in the specific majors, but more by the current “higher labor market returns” and changing social expectations toward “women to act as wage-earners in support of their family” (p. 445). Thus, this study shows the importance of increasing numbers of female students entering a college to study STEM, since once they begin, women are able to resist “chilly climate” faced and continue to complete it similar to women in other majors. Accordingly, they recommended that “focusing on understanding the psychological, social, and interactional processes that function early in the life course to deter females from ever considering or entering such fields, and subsequently designing effective programs and interventions at earlier stages, is likely to be most effective at promoting women’s presence in nontraditional fields” (p. 446). Concerning “chilly climate” at universities, William and Ceci also argued that (1) levels of job satisfaction of female STEM professors were similar to males’ as most of them were “somewhat to very” satisfied (Ceci and Williams, 2011), and (2) faculty of both math-intensive such as engineering and non-math-intensive fields such as biology preferred more women candidates than men (Williams and Ceci, 2015). Thus, they suggested that “it is an auspicious time to be a talented woman launching a STEM tenure-track academic career” (p. 5365).

Summary and implications

As mentioned, the gender issues in STEM are highly related to the lack of future STEM workforces that might affect each country’s economic and societal growth. Accordingly, in this short review paper, we have discussed the issues focusing on factors affecting women’s STEM career aspirations under two broad categories. However, there are still many other topics related to the gender disparities uncovered such as salary gaps between gender (Xu, 2015), academy cultures such as hiring opportunities (Eaton et al., 2020), or levels of gender equality of countries (Stoet and Geary, 2018). Also, Eaton et al. (2020) argued that gender issues in STEM must be addressed with racial perspectives since race also plays a critical role in STEM aspirations that are related to societal structures. However, considering the societal aspects of different countries, the issue becomes much more complex and inconclusive. As McDaniel (2010) argued, in countries where there is more gender equity, more women are expected to be incorporated into higher education. Thus, it is plausible to expect that countries with high levels with gender equality may indicate low gender gaps in terms of STEM aspirations. However, Sikora and Pokropek (2012) and Stoet and Geary (2018) found that gender gaps in students’ aspirations toward traditionally male-dominated fields were revealed more from higher gender-equality societies, like Northern European countries. Sikora and Pokropek (2012) explained this phenomenon based on self-expressive ideologies where advanced industrialized countries hold more than developing countries. On the other hand, Stoet and Geary (2018) described the results based on life-quality pressures as more gender-equal countries tend to have higher levels of social security while less gender-equal countries tend to possess lesser. Consequently, the girls in less gender-equal societies are attracted to focus more on science at school to pursue STEM careers that offer a relatively higher salary. Therefore, it might be important to take actual societal opportunity structures in different societies into account in examining the gender and STEM aspiration issues since the societal structures contribute to shaping career expectations. In addition, what makes it difficult to analyze the gender discrepancy in STEM is that “there are careers that are not STEM by definition, although they often require STEM skills” (Stoet and Geary, 2018, p. 592) such as health care industries including nursing and medicine where women make up the majority. It may describe partly concerning where women with strong STEM skills are located.

Thus, these multiple contributors and their complex interconnections make it a “wicked problem” and hard to give a one-shot solution on the gender issue in STEM fields. However, what many studies argue and agree upon the issue is the importance of early interventions to give proper impressions and information about STEM careers. For this, although special programs for girls may be able to be arranged out of school, it might be more effective to integrate those practices into everyday school science lessons. For instance, hands-on science activities at school are known to be a strong predictor of STEM aspirations both for girls and boys (Kang and Keinonen, 2017) but usually boys lead the inquiry processes actively while girls follow passively (Wieselmann et al., 2020), that might be one of the starting points that girls as well as boys perceive STEM as masculine. Therefore, teachers especially early childhood educators should remind the importance and long-term effects of science practices at school in terms of the gender disparity and should offer equal chances for both girls and boys to be an active participant and leader of the inquiry processes. By doing so, the teachers can give an impression to the young learners as science are gender-neutral and it might be the starting point to redress the gender equity issue in terms of STEM aspirations. Also, as argued by Stoet and Geary (2018) there are many girls who are talented in and enjoy science and mathematics but do not choose the STEM pathway. Thus, when we try to plan special campaigns and programs to increase women’s participation in STEM, it might be effective to target those girls who are obviously being lost but have high potential to return to the STEM pathway rather than targeting other girls who have strengths in another or surplus areas.

Introduction

Indigenous people around the world have struggled to keep their unique approaches to life and traditional knowledge systems intact with the advent of industrialization and, more recently, globalization (Agrawal, 2005). They have adapted and blended their values, beliefs and practices to subsist under a dominant mainstream society (Rogers, 2003). Most of this knowledge has its roots deep in the places they inhabit, and thus is extremely localized. Ethnographers and other social scientists have started to recognize that people in the “non-Western” world have their own science and practices grounded in this knowledge base (Sillitoe et al., 1998). Although indigenous knowledge systems are often very different from the widely accepted western knowledge systems, it has been observed that they play a crucial role in local-level decision-making within areas of agriculture, education, resource management, health care, and many other community-based activities (Kellner and Bosch, 2002).

This chapter discusses how youth in rural communities residing in the middle Himalayas use indigenous knowledge to support environmental decisions while addressing water and land use related concerns. The chapter serves to enrich our understanding of community decision-making, especially as connected to land use and water issues, but also helps us understand how youth in village communities in the Himalayan bioregion negotiate a balance between indigenous and non-indigenous knowledge. The chapter also sheds light on the decision making process situated within the context of the environmental education curriculum “our land our life” (the current environment education curriculum in public schools). The chapter discusses three different aspects of how local communities in Kumaon region negotiate indigenous and non-indigenous knowledge.

1. Identify indigenous knowledge in the Kumaon Himalayas;
2. Find out how much indigenous knowledge youth use for environmental decision making;
3. Discuss relevance of merging knowledge systems to the existing environmental education curriculum “our land our life”.

“Our land our life” and the educational context in the Kumaon Himalayas

With the advent of industrialization and colonization, formal education in most developing nations became a force to produce clerks, administrators and managers. This knowledge system based on western values did not hold the indigenous knowledge system in high regard. Western influxes thus created a myth that indigenous knowledge is unscientific and backward (Gupta,

2007), and the system of transferring indigenous knowledge from one generation to another began to fall apart. As a result, formal education became more classroom-focused, and soon the gap between community and schools began to increase (Niraula, 2007).

This phenomenon of the increasing gap between community and schools exists in the Kumaon region of the Himalayas. In order to help bridge this gap, the Uttarakhand Seva Nidhi (a local NGO) introduced an environment education curriculum into the school system. The curriculum is called *Our Land Our Life* (OLOL). OLOL focuses on local issues, and the embedded pedagogy within the curriculum tries to address the concerns of the rural people in the Kumaon Himalayas. The course currently runs in all the state government schools since the state government of Uttaranchal adopted this curriculum as the official environment education curriculum. The course is implemented from fifth grade to ninth grade (5 yrs) and tries to link people's livelihood issues as related to land, water, fodder, crops, trees and other ecological elements to formal education received in schools.

Even though this existing curriculum links local issues to formal schooling, the gap between communities and school still exists and although OLOL focuses on local environmental issues and discusses these issues within the context of local empowerment, it is the only part of the entire school curriculum that focuses on local issues. Therefore, in the Kumaon region, as well as in other parts of the rural Himalayas, in spite of OLOL being part of the official curriculum, the school is often perceived as an agent that introduces the youth to outside knowledge that is very different from the existing culture and tradition in the region (Jackson, 2003). School education is viewed as a vehicle that provides the youth with resources to help them make a life outside of their village community (Shiva, 2000). The youth who go through a formal education system lack the knowledge about traditional practices that feed into a system that provides sustainable livelihood to the village communities (Goonatilake, 2001). As Pande (2001, p. 48) points out, "In their haste to run away from the village, the young men and women do not seem to have the time to understand their own village and their own people, neither do they receive any orientation toward this in school." For example, in Maichun Village in the Kumaon region, *Palta* was a community activity that involved the entire village community coming together and making compost for their agricultural fields. The practice not only strengthened community bonds but also provided quality fertilizer for agriculture. Jackson (2004, p. 96) observes that "The young youth in the village do not see compost as a resource for sustainable agriculture. In fact, they are ashamed of working on the land: the girls for esthetic reasons (*nail paint would be spoiled* and the *compost stinks*-were some instant remarks from girls) and the boys for livelihood (*what will we do in the village? We go to the city, earn money and live comfortably*-the boys say). Several families in the village now complain of declining agricultural yields, so much so that "food is not even enough for 6 months in a year." The example clearly points out that since the indigenous knowledge is not passed on to the next generation through the intergenerational knowledge transfer system and since most of the formal educational system does not focus on traditional practices, the sustainable livelihood in the village is impacted. Pande (2001, p. 51) also adds, "These impacts were too small to be noticed in the village in the early stages and when they became apparent and obvious for everyone to notice them, it requires resources, the time, and knowledge to regenerate or improve them-a task that nobody in the village can do alone." Therefore, it is important to not only document the existing indigenous knowledge but also in looking at how the villagers might beneficially reincorporate this knowledge into their lives.

Why is indigenous knowledge important to the educational system

Indigenous knowledge (IK) can be defined as the process through which the natives of an area have built a relationship with their natural environment (Semali and Kincheloe, 1999). Thus, indigenous knowledge is developed over time and tied to a certain community. The community can be urban, rural, nomadic, or tribal (IIRR, 1996). Indigenous knowledge (IK) is dynamic, as each generation chooses to adapt the knowledge to suit their needs and values (Agrawal, 2005). But indigenous knowledge is unique to the place and thus is tied to the context. The IK system is often tied to the sustainable livelihood of the people. Generally, the system supports environmental sustainability because it represents generations of observations, analysis, and experimentation. IK provides a powerful problem-solving mechanism for local communities (Tella, 2007).

Understanding IK in traditional communities is fundamental to the design of any learning environment in the Kumaon region of the Himalayas (IIRR, 1996). Learning environments have to take into consideration several aspects of community. These include the community of the classroom, the school, and the connections between the school and the larger community, including the home. The importance of out-of-school learning becomes clear when one examines the relatively small amount of time spent in school compared to other settings. Activities in homes, community centers, and after-school clubs can have important effects on students' academic achievement (Bell et al., 2006). In the Kumaon region, learning also takes place when youth work on family farms, take cattle out for grazing and do landscape related work. Thus the effective instruction begins with taking into account what learners bring to the setting; this includes cultural practices and beliefs as well as knowledge of academic content. There are many studies that have shown that what people learn and how people learn is context-dependent (Mertl et al., 2007). Therefore, a learning environment that takes into consideration the context should help learners link ideas from ecology and formal science to their own lives (Burford et al., 2005). Finally, an educational initiative on sustainability that embraces IK would help learners negotiate different worldviews and value systems about development and livelihood (Palmer, 1998).

What is the existing indigenous knowledge in the Kumoan Himalayas

The issue of identifying knowledge types (indigenous, traditional ecological knowledge (TEK) or exogenous) is a complex process. There is very rarely a single instance that can be one knowledge type or another. In most instances there is an overlap. Semali and Kincheloe (1999) address this issue of complexity by pointing out that “Indigenous knowledge is an ambiguous topic that immediately places analysts on a dangerous terrain. Not only are scholars unsure what we’re talking about but many analysts are uncertain who should be talking about it.” Thus the first step is to ensure that there is consensus about the “definition” of indigenous knowledge/traditional ecological knowledge. Using the Delphi technique we identified what people in the region consider indigenous knowledge that can help with land and water resource management. The Delphi technique was used to facilitate information, opinions and judgments from a panel of experts to gain consensus on the issue of what Indigenous knowledge can be used to manage land and water resources (Dunham, 1996). The reason to focus on the above two issues was made because water—and land-related issues are important issues that are directly related to the livelihood and the quality of life of people in the region which relate to indigenous practices and maintain relevance today. Also water and land related issues have been identified by prior work in the region as key concerns, both by government and nonprofit workers, and by local inhabitants. Water touches every aspect of human life and, if not managed well, can create hardships. Similarly good land management practices are important so as to provide the people with food and shelter. By focusing on the types of knowledge people use to manage land and water, we were able to make suggestions toward designing better environmental education programs for helping communities in the region better their quality of life.

Thirteen participants/experts were identified and were requested to participate in this Delphi process. The participation was voluntary and no compensation was offered. The participants/experts were chosen by consulting with the officials of the Uttarakhand Seva Nidhi Paryavaran Shikshan Sanstha (Uttarakhand Environment Education Center—UEEC). The criteria for the selection of the participants were that the individuals would have experience working with the local communities on social, agricultural, economic and related environmental issues.

The Delphi procedure was carried out in three rounds. The first round the participants were asked three sets of questions. These questions were asked in interview format in Hindi and in English and were recorded on video. The questions were as follows:

1. What is your definition of indigenous knowledge?
2. What are some practices that use indigenous knowledge for water management? What is the specific indigenous knowledge used within these practices?
3. What are some practices that use indigenous knowledge for land management (as related mostly to forests and agriculture)? What is the specific indigenous knowledge used within these practices?

Results of the Delphi

The answers of all of the 13 participants were conceptually similar but keeping in mind that there was consensus for answer sheet/participant number 1, the answers given by this participant were taken as the result for research question number 1 and as the concluding result for the Delphi.

The results on the consensus building exercise (Delphi) was as follows:

Question 1 on the Delphi

What is your definition of indigenous knowledge?

Indigenous knowledge is knowledge that comes to you from your ancestors and that has evolved over time. It is knowledge that is attached to a certain place. Also there is a difference between traditional knowledge and traditional practices. Sometime when we follow a practice without understanding the logic behind the practice that is traditional practice, the actual logic behind the practice is traditional knowledge.

Question 2 on the Delphi

What are some practices that use indigenous knowledge for water management? What is the specific indigenous knowledge used within these practices?

1. Water is the basic necessity for life. The example of how the community traditionally manages water is “Naulas” (ground water springs). There is traditional knowledge associated with how to build a Naula. The structure is very important. The structure is such that it helps the ground water come to the surface and then stay above the surface.
2. The second thing that traditional knowledge does to manage water is keep the water sources clean. Often times the water sources are designated as religious and thus people have to go in them barefoot, which helps in keeping the source clean.
3. Collecting rainwater is another way we can manage water traditionally.

4. People used to plant native species (Oak and Deodhar) to make sure that there is maximum seepage of water into the soil, as planting these trees helps hold the soil together, thus leading to more water seepage into the ground and increasing the ground water table.
5. Digging trenches (khals) is another way to manage the water.
6. People also build small dams (choys) to stop flowing water
7. To keep the soil together and to help stop water runoff people around here build depressions (guls) around their farms.
8. There are traditional devices (Earthen pots) to store water and keep it clean.
9. There is encouragement to use running water rather than stored water because the logic is that running water has a natural filtration system

Question 3 on the Delphi

What are some practices that use indigenous knowledge for land management (as related mostly to forests and agriculture)? What is the specific indigenous knowledge used within these practices?

To keep the land healthy people use the following traditional practices:

1. Using organic compost.
2. Seed saving is traditionally considered good land management practice.
3. Mixed farming and crop rotation practices keep the land healthy.
4. Healthy forest keeps the farms healthy by providing more organic litter for decomposition, to make good compost.
5. Not cutting an entire tree for fodder. Cutting the lower branches of the tree keeps the tree from destruction and the more healthy the trees, the healthier the soil and better yield from the land.
6. Sharing labor for agriculture is a good land management practice as there is community participation and thus makes sure everyone keeps their piece of land healthy and bad practices do not spread.
7. Use organic pesticides and insecticides such as walnut leaves and neem leaves.

Thus the first part of the study helped identify and document the IK in the region.

Shortcomings of the Delphi panel

Although the Delphi panel identified indigenous knowledge and practices, we do not believe that they have identified all of the practices that are indigenous to the region. An example of this is the practice of community discussions to resolve issues faced by the community as a whole. The Delphi panel has not identified this practice as indigenous. But village communities are often times known to get together to resolve an issue faced by their community. The government of India in an attempt to restore traditional practices in village communities encourages *Panchayat Raj*, a form of local government that involves community discussions and resolving issues at community level. While this specific form of community discussion forum (Panchayat Raj) may not exist in the Kumaon region, other forms of community discussion forums may exist within the region. The issue is thus nuanced and complex. The practice of using formal community discussions to resolve issues may have existed in the past (before the British rule). It is documented that community discussion forums or *village sabhas* were part of society until 600 BCE (Mathew, 2000). After this, the subcontinent was broken up and different rulers/kings governed different parts (Mathew, 2000). During the British rule (which lasted about 150 yrs) all forms of local problem solving mechanisms were dismantled (Mathew, 2000). It was only after India regained independence that the local village governing systems were put back into practice. Thus the local community discussion forums exist in a different form than the ones that existed in pre British India, which brings up the issue of how indigenous practices evolve over time. The issue of the evolution of indigenous knowledge will be discussed later in the paper. For the purposes of this study, we have identified complex practices such as community discussions as a non-indigenous practice, not only because the Delphi panel did not identify it as indigenous knowledge or practice but also because the practice itself does not exist in its original form. There is documentation (Shiva, 2000) about how the caste system has hijacked the practice of community discussion forums, where upper caste members have an upper hand in decision-making processes. Thus since it does not exist in its true indigenous form, I have identified it as a non-indigenous practice.

Also some of the practices that the panel has identified as indigenous can also be identified as a part of the modern conservation movement that has been based on western ecosystem science. One prominent example is that of the practice of planting trees. The Delphi panel identified planting trees as an indigenous practice. This practice can be seen advocated in the modern conservation movement. The practice stemmed from the excessive deforestation that took place for developmental purposes. As the industrialization took priority, deforestation took place at a rate that was unsustainable and thus it gave rise to the need of tree planting (Govinda and Diwan, 2003). However, this is also an indigenous practice and is suggested to be a part of the sacred grove concept, where communities planted trees to appease the gods (Bhagwat et al., 2005). Thus for the purposes of this study, we have identified this particular practice of planting trees as indigenous knowledge.

We recognize that the issue of “what is indigenous and what is not” is far more complicated than the scope of this particular study, but the Delphi panel does provide a means to construct a reasonable list of indigenous practices within the region.

Use of IK by youth for environmental decision-making

The participants for the study were recruited from two villages east of the city of Almora. The first village was Chanoli and the second village was Maichun. The youth were recruited from two different high schools. The first school was Panvanaula high school and inter-college and the second school was the Garudabanj high school and inter-college (In India, high school runs through 10th grade, while inter college includes grades 11 and 12). Both these schools are run by the state government. Youth from Chanoli and Maichun attend the Panvanaula high school and inter college. The youth participation in the study was voluntary. Overall a total of 29 youth participated in this phase of the study. There were three main techniques used to identify youth's knowledge of the IK and the youth's use of IK for decision-making.

These three techniques are as follows:

- Focus groups: The student groups (5–10) students were identified with the help of the teachers.
- Role-play activity: a role-play activity was designed for the students in the focus groups. By having the students assume certain roles of stakeholders involved in the local decision-making processes, the students' ideas of how these processes function and what types of information is used was assessed.
- Semi-structured interviews: Semi-structured interviews provided useful information on how much IK they know and how they would use IK for potential decision making processes.

Coding the interviews and the focus group discussions

A total of 29 interviews were conducted with students from both the schools (13 from Garudabanj and 16 from Panvanaula). We also conducted three focus groups with the youth in the Panvanaula school and 4 focus groups with the youth in the Garudabanj school. Once all of the interviews and focus groups were transcribed every utterance was coded for the use of indigenous knowledge as identified by the Delphi.

The main categories of Indigenous knowledge for which every utterance was coded were as follows:

Traditional/indigenous knowledge with respect to water as found out in the results of the Delphi:

1. Use of *Naulas* (ground water springs)
2. Keeping water source clean.
3. Rain water harvesting.
4. Plant native species of trees (Oak and Deodhar)
5. Digging trenches (khals)
6. Build small dams –(choys)
7. Build depressions – (guls around their farms)
8. Use traditional devices to store water and keep it clean.
9. Use running water rather than stored water

Traditional/indigenous knowledge with respect to land management as found out in the results of the Delphi:

1. Using organic compost.
2. Seed saving is traditionally considered good land management practice.
3. Mixed farming and crop rotation practices.
4. Healthy forest keeps the farms healthy
5. Not cutting the entire tree. Cutting the lower branches.
6. Sharing labor for agriculture.
7. Use organic pesticides and insecticides such as walnut leaves and neem leaves.

The following is an example of the complete coding system with the main and the sub categories:

Participant: If the tap water runs out we go to the village leaders or government official and get them to fix the problem and in the mean time use the water from the naulas.

This utterance was coded for the main traditional knowledge category as **Use of naulas** and the utterance was further coded as **aware but do not think of as a viable solution to resolve the problem – 2**. The reason why this utterance was coded as 2 is because although the participant is using the naula, he/she feels like the solution to resolving their problem is that the government should fix the tap. A category 1 **Aware and think of as a viable solution** utterance is as follows *"We should use the naula water and take care of the naula"* and a category 3 utterance is *"We use the naula and the tap water as the tap water is convenient but we cannot use it for drinking, we prefer the naula water for drinking."*

After coding for traditional/indigenous knowledge use, The data was coded for other solutions. These solutions were called exogenous or non-traditional solutions. There were several of these other/exogenous/non traditional solutions that were offered by the youth. The main categories of exogenous/nontraditional solutions that the youth offered to resolve water problems in the village were as follows:

1. Educate the community members
2. Sit together for a meeting and collectively solve the problem.

3. Since youth study these issues in school adults need to listen to them.
4. Manage cattle grazing.
5. Petition the government/village chief to resolve the water issues.
6. Stop corruption
7. Build hand pumps and wells.
8. Maintain and repair existing pipelines.
9. Distribute/Ration water.

Since all the participants who mentioned these solutions thought of them as viable solutions, the utterances were sub-coded as 1- **Aware and think of as viable solution** and 4- **Did not mention at all**.

There were not many non-traditional solutions presented by participants to resolve some of the land management issues. Some of the non-traditional solutions presented by the youth to resolve the land related problems were:

1. Stop pollution
2. Human population control
3. Stop migration toward the city.

Results

Overall the youth indicated that the following solutions were important to address water and land related issues.

Water management (IK)

The number one solution that the students present in terms of managing water using indigenous knowledge is tree planting. In the focus groups (100%) and the interviews (83%), the students strongly stressed the need to plant native species of trees in order to hold the soil and increase water seepage into the ground water table.

Rain water harvesting, use of *naulas*, keeping water sources clean, and proper water storage were some other solutions that the students presented to solve the water issues in the community. Although aware of these traditional practices, not all of the students felt like these were viable solutions to resolve the problems related to water management.

Land management (IK)

The majority of the students during focus groups (86%) and interviews (83%) thought the practice of not cutting trees in their entirety is a solution to helping resolve land related environment problems. During focus group discussions, some students (14%) also thought that mixed farming, crop rotation, use of organic fertilizer, use of organic insecticide and seed saving are solutions to resolving land related issues. While during interviews, (7%) of students thought crop rotation and mixed farming were practices that lead to lesser land related problems. Also during interviews, (3%) of students thought using organic insecticide and fertilizer are good solutions to resolving land related problems faced by their community.

When it came to resolving land related issues, the students did not present many exogenous solutions to actively resolve the land related problems.

Focus groups (water)

During the focus groups the youth focused on following solutions for addressing water and land related issues:

The top two choices that youth mentioned as solutions to resolving water problems in their village are planting trees (100%) (native species, broad leaf trees –oak, deodhar, etc.) and keeping the water source clean (57.1%). Both of these are indigenous knowledge sources as indicated by the Delphi panel. Resolving problems through community discussions and meetings (57.1%) is also a top choice the students made to resolve water related problems faced by the community. This choice is based on outside knowledge as the Delphi panel did not identify it as indigenous knowledge. However, community meetings and problem solving is a known indigenous method in rural India (Shiva, 2000).

Also rain water harvesting (indigenous knowledge) and educating community members (outside knowledge) regarding water conservation and management issues were other choices made by 42.9% of students. 28.6% of students thought that using *naulas* (indigenous knowledge) and proper water storage devices (indigenous knowledge) was a good idea to solve some of the water related problems face by their community. This was followed by 14.3% of students suggesting that digging trenches (indigenous knowledge), adults listening to youth (exogenous knowledge), putting a halt to corruption (exogenous knowledge) and constructing new hand pumps and wells (exogenous knowledge) as ways to resolve water related problems faced by their communities.

Interviews (water)

The individual interviews also put forward a similar story as the focus groups. The top two choices that the students have indicated as practices to resolve water problems face by their community are planting trees (native species—broad leaf trees like oak and deodhar)—82.8% and keeping the water source clean (24.1%). Both of these are identified by the Delphi group as practices supported by indigenous/traditional knowledge. 20.7% of students think educating community members (outside knowledge/exogenous knowledge) is a good idea to resolve some of the water related problems in their community, and 13.8% of students think rain water harvesting (indigenous knowledge) is a good idea to resolve some of the water related problems faced by their communities. 10.3% of students think that proper water storage devices (indigenous knowledge), building new pipelines and repairing existing pipelines (exogenous knowledge) and fair distribution of water are good solutions to resolving water related problems faced by their communities. 6.9% of students think building small dams choys (indigenous knowledge) is a good idea while 3.4% of students think solving water related problems should include building hand pumps and wells (outside knowledge), asking the government to intervene (outside knowledge) and using *naulas* (indigenous knowledge). 6.9% of students think that their community should supplement the new methods such as pipes with traditional methods such as *naulas* to resolve some of the water related problems.

Focus groups (land)

As in the water related focus groups and interviews, the students used a combination of outside knowledge and indigenous knowledge to make their decisions with regards to issues presented to them in relation to the land in their community.

The top choice that the students have mentioned as solutions to resolving land related problems in their village are not cutting trees (85.7%) This is a practice based on indigenous knowledge sources as indicated by the Delphi panel. 14.3% of youth thought that keeping the forests healthy (indigenous knowledge), mixed farming (indigenous knowledge), seed saving (indigenous knowledge), organic insecticide use (indigenous knowledge) and crop rotation (indigenous knowledge) are good land management practices, and these should be used to resolve land related problems in their communities.

6.6% of students suggested that stopping pollution (exogenous knowledge) is a solution to resolving land related problems and 3.3% of students suggested population growth control (exogenous knowledge) as a solution to resolving land related problems face by their community. 14.3% of students thought mixing organic pesticides with new artificial pesticides was a solution to resolving some of the land related problems.

Interviews (land)

During individual interviews, 82.8% of students offered not cutting trees (indigenous knowledge) as a solution to resolving land related problems. The next best choice was to stop pollution (exogenous knowledge)—42.9%, followed by Crop rotation (indigenous knowledge)—14.3% and stopping out migration (exogenous knowledge)—14.3%.

6.9% of students suggested mixed farming (indigenous knowledge) and using organic insecticide (indigenous knowledge) as solutions to some of the land related problems. These were followed by 3.4% of students suggesting that keeping forests healthy (indigenous knowledge), using organic fertilizer (indigenous knowledge) and seed saving practices (indigenous knowledge) were good solutions to some of the land related problems in their community.

Other related results

In order to get the complete picture of how much knowledge is passed on to the youth and how much of this knowledge youth use to make current or potential decisions about the land and water situation in their village, it was also important to find out where is the source of all of this knowledge. Thus when asked the question “where did you learn about this specific practice?” 72.4% of students said that they learned all of their knowledge in the school, 13.8% identified the source of their knowledge as home, and 3.4% of students indicated that some of the knowledge they learned at home and some of it in school.

Discussion and conclusion

When asked about how they would go about solving water-related problems in their community, almost all of the students said that planting trees (native species) is the most important step. Their explanation for this was that the trees would hold the soil, which in turn will stop water runoff and increase groundwater tables so that the springs and rivers will have more water. This explanation corresponds to the explanation given for planting native species of trees in their environmental education curriculum *Our Land, Our Life*. The students also mentioned using *naulas*, harvesting rainwater, utilizing proper water storage and keeping water sources clean as other ways to resolve water-related issues. In terms of land related issues majority of the youth thought that not cutting trees in their entirety was the number one solution to resolve land-related issues. The explanation behind this solution was that cutting trees would lead to deforestation and thus will cause soil runoff, which would be harmful to the land. Other than the above, a few youth mentioned mixed farming, crop rotation, the use of organic insecticide, and seed-saving as solutions for resolving land-related problems in their community. Most students indicated that currently, they would use practices based on indigenous knowledge to resolve some of the water- and land-

related issues in their community. It also appears that the youth are aware and recommend certain practices based on indigenous knowledge to resolve issues related to water in their community and that they have learned about the majority of these practices in school. Based on their answers it also appears that the environment education curriculum "our land our life" is a major source of the knowledge that the youth are projecting when asked to solve water and land related environmental problems. This is reflected in the data where 72.4% of students mentioned that they learned most of these practices in school, and 13.8% of students indicated that they learned some of the practices at home and some at school.

However, the findings also indicate that even though the youth mention that most of the practices that they will use in resolving water- and land-related issues are traditional practices, it is not completely guaranteed that they would use them to resolve these issues in reality. This observation is supported by the data that indicates that when asked whether they prefer tap water or water from the naula, 95% of students said that they would prefer tap water. Jackson (2008) also addresses this issue of students not wanting to indulge in traditional practices, by pointing out that young people are more likely to choose urban/westernized ways of doing things when presented with a choice. Several families in the village now complain of declining agricultural yields, so much so that food is not even enough for 6 months in a year." This quote implies that the students do not want to indulge in the traditional practices.

It is not surprising that the students are indicating that they have learned about resolving water and land related issues from their curriculum *Our Land, Our Life*. *Our Land, Our Life* is a powerful curriculum developed by the Uttarakhand Seva Nidhi Paryavaran Shikshan Sanstha, a non-governmental organization working in the Kumaon ranges of the Himalayas. The curriculum tries to link classroom with actual environmental problems, identifying links between issues that reflect real-world situations and relating environmental education to the local community. The curriculum addresses not only environmental science but also environmental education for sustainability more generally. The curriculum was developed in a unique partnership with local villages and has a focus on indigenous knowledge. It may be possible that the curriculum *Our Land, Our Life* presents them with solutions that do not fit their reality. It also is possible that the youth gave the answers they have learned in school since the interviews were conducted in the school.

The question that arises is that how well the environmental education curriculum has fit the changing nature of the communities. The demographic of the village community has changed over time. The men in the villages often go to the urban centers to seek better economic opportunities (Pande, 2001). There is a need within these communities to urbanize, as that is recognized as being developed (Agrawal, 2005). Thus indigenous knowledge practices are often times adapted to the needs of development and urbanization. However, in the school, the youth are learning about indigenous knowledge systems and about how these knowledge systems are sustainable because they fit the context. So on one hand at home there is a push toward being more urbanized while on the other hand at school there is a push toward indigenous practices. This struggle shows in the data as the youth are not voicing the actual changes experienced within their communities.

There is also the issue of changing nature of indigenous knowledge systems. Along with changing communities the knowledge also changes. With immigration and emigration of knowledge the complexity surrounding what knowledge is indigenous for a particular generation remains a question that is yet to be answered. The Delphi panel has provided a starting point for the discussion of what is the indigenous knowledge in the region, and how indigenous is it? Although the study directly does not ask these questions, we feel they are questions that need to be addressed as communities that associate with this knowledge move in time and space. For example, the men in the village are oftentimes employed in the urban areas and interact with urban resources such as water taps. When they come back to the village, they seek these urban conveniences and try to adapt these conveniences to their context and culture. Thus in the process they add to the existing traditional knowledge systems. These adaptations are not always sustainable, but every once in while an adaptation such as a water tap next to a house becomes a sustainable practice. Then the question arises, when should we identify the water tap as indigenous. This is a complex question that is beyond the scope of this study, but like a restoration ecologist struggles with, how far back in time one should go in order to restore the ecosystem to its "native" state, similarly there is a struggle here as to how far back in time we should go in order to identify a knowledge practice as indigenous. The way indigenous knowledge evolves, and what constitutes indigenous knowledge, is a complex study that will require a different set of probes. But as we acknowledge the complexity of this issue, we would also like to state that we have tried to address the complexity of what is indigenous knowledge by gaining consensus from local experts. The Delphi panel does not address every single level of complexity of how these knowledge systems are constructed but provides a starting point and a good insight into the indigenous knowledge systems.

The school curriculum *Our Land, Our Life* needs to fit the changing face of knowledge. The curriculum needs to recognize that people move through time and space and knowledge itself will evolve over a period of time. If the curriculum hopes to revive the traditional knowledge systems within the youth without acknowledging the evolution of the knowledge base then we think there is a fair chance of it being rejected. Especially since the teachers (who come from an urban area) think of this curriculum as not "up to date" (field observations, 2005, 2006, 2007, 2008). By not recognizing the changing landscape of the indigenous knowledge systems, the curriculum is working against the intergenerational knowledge transfer. Especially since the knowledge the youth are getting at home is different from the knowledge they are learning in school.

The other relevant observation is that the youth were much more confident in presenting solutions to resolve water problems. When it came to answering questions related to resolving land issues, most youth seemed like they did not know much about how to resolve them, and thus used the information from their curriculum *Our Land, Our Life* to answer the question. This could be because most of the youth who go to school do not go into the fields with their parents (or their parents are not farmers). However, they use water daily and are much more aware of water-related issues than land-related issues.

Although *Our Land, Our Life* is a powerful curriculum that focuses on local indigenous practices, it needs to take into consideration the evolving nature of indigenous knowledge and the applicability of this knowledge. For example, newer ecological problems have arisen during the past 20 years. With problems such as climate change looming over the Himalayan communities, the curriculum needs to focus on adaptability rather than only indigenous knowledge. There is no indigenous knowledge that exists to deal with current environmental problems such as climate change. Thus the curriculum needs to keep up with the changing ecosystem to create solutions based on the evolution of indigenous knowledge.

In summary our data and observations suggest that the students are aware of the indigenous practices and some of the scientific reasons behind these practices but are less likely to use them in reality. There is evidence that youth are learning about different practices at the school and at home, but at this time they are unable to build bridges so as to carefully integrate the knowledge that they gain in all of these different settings. They seem to be thinking that the knowledge from home is not useful in school, and in school, they should only discuss things that they learn in the school curriculum.

It is important to bridge the gap between formal and informal learning as learners are constantly making sense of their environment in formal and as well as informal environments (Bransford et al., 2006). Thus, if the students do not connect in-school (formal) learning to what they learn at home (informal), then the students are going to find it difficult to construct scientifically sound and meaningful knowledge. The students' underdeveloped conceptual ecology with respect to environmental problem-solving solutions is certainly going to hamper the students' decision-making process. Thus, in order to close the gap between formal and informal learning and empower the students to make environmentally sound decisions about their local environment in the future, the designers of the curriculum *Our Land, Our Life* need to restructure the content of this curriculum. The curriculum itself needs to be realigned with the current environmental situation of the Kumaon Himalayas. This can be achieved by:

1. Evaluating the current environmental situation in the villages: This has to be done as problems such as global warming are starting to create severe water problems in the Himalayas, and these new environmental problems need new strategies of adaptation and survival.
2. Restructuring the curriculum *Our Land, Our Life* based on the environmental evaluation.
3. Conducting long-term ethnographic research with students to assess long-term learning and application of knowledge.
4. Preparing iterations of the curriculum based on these long-term studies.
5. Connecting the curriculum to other subjects and making it a true interdisciplinary curriculum. This would also involve organizing teacher trainings to have subject teachers collaborate with each other.

As the climate changes, the water and land resources in the Himalayas are changing at a rapid rate. There need to be strategies in place to help people in the Kumaon region cope with these changing times. The recommendations above are just a start, and there is plenty of more research and action needed to help the mountain environment and the communities that reside in the Kumaon Himalayas cope and adapt to the changing ecology of the Himalayas.

The global nexus of STEM education and workforce development

STEM workforce development is at once a nation-specific and a global enterprise. A nation's competitiveness and level of development are typically considered dependent on the strength of its science and technology capacity (e.g., [Romer, 1994](#)), and thus policy makers focus on various metrics about a nation's STEM workforces as indicative of its economic prowess. Similarly, the global migration of students and high-skilled workers has become an issue of national and international policy: "Receiving" countries encourage immigration into their colleges and STEM workforces, while "sending" nations view the loss of their potential workforce as a continuation of brain drain. However, some nations, such as India, have found global migration important for their outsourcing technology industries, or in the case of China, as a means of developing a high-skill workforce trained in cutting edge technology and science that can be recruited back to contribute to its own economic and technological development ([Lynn et al., 2012](#); [Lynn and Salzman, 2018](#); [Meil and Salzman, 2017](#); [Saxenian, 2006](#)).

Although STEM workforce development systems are integrated into a global network, they function differently around the world depending on the structure and quality of each nation's education system and the types of businesses in each country, along with national policies. Moreover, perspectives differ on whether each country's STEM system provides global or only national benefits. This debate has become a contentious public policy issue in the United States, where large global flows of STEM students and workers have become an integral component of its STEM workforce system. But too often these policy debates rest on simplistic notions about the role of STEM education and the STEM workforce, along with misconceptions about "national competitiveness" in these global systems. As a consequence, STEM and education policies often have the paradoxical effect of undermining a nation's, and the world's STEM workforce development and capacity.

Historically, nations benefitted from migration that contributed to their economic and social development and the STEM fields, in particular, benefited from selective global migration. In recent years, the creation of targeted and nonimmigrant education and work programs has again become a matter of policy and legislative debate. Scholars and lawmakers question whether some transnational flows of students and workers are counterproductive to the nation's indigenous STEM strength—either in loss of workers or in weakening labor markets in the receiving countries ([Borjas, 2016](#)) even if large supplies of guestworkers are profitable for individual firms. For example, the US Department of Labor calculates that the H-1B nonimmigrant temporary visa program, by supplying technology guestworkers at below market wages, creates a transfer payment from forgone worker wages to employers of \$3 billion to \$4 billion annually ([Employment and Training Administration, 2021](#)). As such, historical patterns of STEM education and workforce development may be changing, with different impacts from those of the past.

Further complicating simple formulations about the role of STEM workforce development in a nation's economy is the complex nature of global interdependencies in technology development. In the US, simplistic analyses have used metrics such as the number of engineering graduates to assess a country's presumed advantage or "competitiveness." The use of such indicators has led to dramatic proclamations: first, that the Soviet Union's large math and engineering cohorts would enable it to overtake US science and technology innovation; then a fear that Japan's prodigious engineer production would lead to its global dominance and, in the past decade, fears that China's large number of engineering graduates will imperil US competitiveness ([National Academy of Sciences et al., 2007](#); [Teitelbaum, 2014](#)). In these cases, the reports used questionable metrics and comparisons ([Berliner and Biddle, 1997](#); [Salzman and Lowell, 2008](#)) but, more importantly, they failed to consider the role of different STEM workforces in each

country's development. The number of engineers, for example, largely reflects the amount of construction in the country, however building roads, housing and factories is not considered an indicator of a nation's "global competitiveness" or innovation capacity (Lynn and Salzman, 2010; Kuehn and Salzman, 2018).

At the same time, a globally integrated STEM education system can provide strong global linkages in innovation networks, can facilitate the "sending" country's development through educating and training its workforce, and/or can contribute to global networks that enable outsourcing and offshoring. Such globalization can increase the fortunes of a firm while weakening the economy or welfare of its home country. Although the global STEM development system depends on industrialized countries' STEM education systems to supply globalized STEM enterprises, those "host" countries may not be the beneficiaries if firms globalize work or engage in global labor arbitrage to lower wages (Hira, 2008; Lynn and Salzman, 2018).

There is another challenge in aligning STEM education and workforce development: educational institutions vary greatly between and within countries, as do pedagogical practices. But STEM disciplines are assumed to largely, or at least conceptually, transcend national borders or politics. Thus, while education is a global enterprise, workforce development is largely a national initiative. As such, STEM education and workforce development have distinct, if interrelated purposes and are shaped by a complex set of national policies and global migration and economic activity. The focus of this chapter is on STEM education and workforce development in the United States in the context of global education migration and global enterprises that employ STEM graduates from US universities.

Political history of STEM education and the workforce

The need to educate and train students and workers to take up careers in fields now collectively referred to as STEM has been a long-standing concern of educators, development practitioners, analysts, and policymakers around the world. While STEM acronymically refers to Science, Technology, Engineering, and Mathematics, the meaning of STEM as a category of education, training, and occupations has evolved over time, as has the focus of related policymaking.

The STEM history as an acronym dates to circa 2001 when it was rearranged from its earlier formulation as "SMET" by the National Science Foundation (NSF), which was the successor to NSF's traditional classification, Science and Engineering (S&E). But STEM's pre-history begins shortly after the end of World War II, when science and engineering were recognized as vital to strengthening military capabilities. The destructive force of the Atomic Bomb was the most visible scientific achievement, but the second world war was fought with a vast number of scientific and technological advances, from radar and sonar to cryptography and operations management and logistics developed by the military's statistician "Whiz Kids". A new generation of military leaders and policy makers began to actively pursue an expanded role for government in scientific and technological development. This goal was immediately linked to a need to train a substantial supply of people who "understand the fundamental laws of nature and are skilled in the techniques of scientific research" (Bush, 1945; Zachary, 1999). And thus, in the mid-1950s, Congress asked the National Academies of Sciences to regularly conduct a census of the science and engineering workforce to have an ongoing assessment of the nation's science and technology capacity. Having sufficient numbers of scientists and engineers would be vital should there be another Manhattan project—which had developed the Atomic Bomb—and more generally necessary to advance the civilian and military development envisioned by the President's science adviser in the *Endless Frontier* (Bush, 1945).

From the beginning, the expansion of STEM supply was viewed as necessary not just for the military, but also for the private sector and advancing the nation's standard of living. Similarly, this period was the start of a perennial complaint that a wide range of the nation's ills—from military and economic weakness to an inability to compete with the technological prowess of, first the Soviet Union and later various Asian nations—came from the failure to produce enough graduates in mathematics, engineering and the sciences. In 1958, a five-part series in *Life* magazine compared the educational environments of two students, one in the US, the other in the Soviet Union, depicting the US school system as relatively lax and unfocused—particularly in the sciences. It appears this story was designed to raise Cold War fears, and it may not have been a faithful piece of journalism. Among a number of distortions, the Soviet student was likely a fiction of *Life* magazine (Bracey, 2009, p. 43), and the articles served to further its ultraconservative ideologue publisher Henry Luce's broader policy efforts to raise public fears about the Red Menace (Brinkley, 2010). Luce, along with other policymakers and corporate leaders, was battling President Eisenhower's efforts to reduce military spending and improve diplomatic relations with the Soviet Union. The attack on US education was part of the effort to shift US policy to confrontation with the Soviet Union by containing liberal arts education in the US that was, Luce argued, leading youth to question a hardline anti-Soviet attitude and toward liberal politics more generally (Bracey, 2009).

The most remembered, and misremembered event of the period was the successful launch of the *Sputnik* satellite in 1957 as part of the International Geophysical Year. Although the Soviet launch preceded by several months the American launch of a satellite that had a scientific mission, the political fallout lasted decades. Both nations had entered the International Geophysical Year (IGY) in 1957 with the jointly announced goal of each launching a satellite as global scientific and technological projects during IGY. The Soviets then sought the public relations coup of first-to-launch with an abbreviated scientific and technological mission. The US satellite that launched a few months later, the Jet Propulsion Lab's Explorer 1, had a cosmic ray detector that confirmed what became known as the Van Allen radiation belt. A month and a half after that, Vanguard I went into orbit to transmit upper atmosphere measurements, continuing to relay information for six years, and is still orbiting today. *Sputnik* was in orbit for three months and had only a beeping transmitter that sent a radio signal for a mere three weeks and provided no scientific information. Like much of STEM policy over the decades, the narrative of weakness and failure that

emerged from Sputnik had little correspondence to the evidence; Soviet satellite strength was transitory and overplayed, as was its technological and economic prowess more generally. Nonetheless, the STEM myths based on fear had a more important role than evidence in shaping US policies.

In 1958, Congressional education leaders, notably Alabama's Senator Lister Hill and Representative Carl Elliot were, after a decade of failed attempts, finally able to broker a political compromise to steer federal funds into education systems. Labeled the National Defense Education Act (NDEA), thrice-defeated federal education legislation was revived and, after a year of lobbying and public campaigns such as the *Life* magazine series, these Alabama congressmen navigated a difficult legislative path providing federal funds to schools that were controlled by states and local school boards without fear of federal regulation in matters such as desegregation following the 1955 *Brown v. Board of Education* Supreme Court ruling (Urban, 2010).

The NDEA provided funding for school buildings and programs in sciences and foreign languages. It provided federal support for higher education in the form of loans and fellowships with a priority to sciences and foreign languages, though a wide range of fields were supported as long as the college would administer loyalty oaths to its students; 166 colleges, however, publicly protested the provision, with 32 turning down all NDEA funding, including Harvard, Yale and Princeton (Clowse, 1982). Although the passage of NDEA is regarded as addressing a science and engineering shortage, the legislation came on the heels of the 1957 publication of a landmark study of *The Demand and Supply of Scientific Personnel* by National Bureau of Economic Research labor economists Blank and Stigler, who found no such shortage (Blank and Stigler, 1957).

Global politics have continued to be an integral part of the narrative about the importance of STEM and proposed legislative responses. As further history shows, global threats and claimed weaknesses are perennial, never solved, and conveniently raised to advance other political goals. It was thus, two decades later following a period of economic doldrums and declines in military spending and prestige that education once again took center stage in the nation's failures. The 1983 report entitled *A Nation at Risk* identified US schools as responsible for "the educational foundations of our society presently being eroded by a rising tide of mediocrity that threatens our very future as a Nation and a people If an unfriendly foreign power had attempted to impose on America the mediocre educational performance that exists today, we might well have viewed it as an act of war" (National Commission on Excellence in Education, 1983). Perhaps not unintentionally, the report coincided with Reagan's highly controversial arms build-up through unprecedented peace-time deficit spending and funding for fantastical outer space technology development dubbed the "Star Wars" defense system, taking aim at the Soviet Union.

Once again, an educational failure report was followed by a serious study of the evidence that found the report's claims lacking. Most notably, the Department of Energy's Sandia Laboratories reexamination found the evidence weak and in error, and the prose hyperbolic (Carson et al., 1993). Nonetheless, the *Nation At Risk* report fueled proclamations of educational failure as the pivotal explanation for the economic declines of the previous decade (Freeman and Salzman, 2018; Weinstein, 1998) and added to the general fear of the Soviet Union.

In 2005, during the Bush administration's efforts to expand vouchers and charter schools to privatize education (Ravitch, 2020, 2014), and during a period of public doubt about the nation's military standing in the world, another commission rushed out a report that bore a title refashioned from Churchill's warning of *The Gathering Storm* about the Third Reich's ascendancy. The National Academies report, *Rising Above the Gathering Storm*, (RAGS), led by a defense contractor's retired CEO, advanced a similar argument to earlier reports—that US schools were failing in math and science relative to other countries, and that massive investment was needed in these subjects to maintain competitive advantage in an increasingly technology-driven global economy (National Academy of Sciences et al., 2007). The report's findings were echoed by numerous industry association reports and policy briefs, and provided support for Congress's passage of the America Competes Act in 2007. The Act had a broad agenda of funding science and technology research, and increasing NSF's budget, along with renewed emphasis on expanding the supply of STEM workers, especially increasing the supply of guestworkers, in response to a claimed shortage. At the same time, and once again, careful reviews of the evidence found the claimed shortages and loss of international competitiveness—to China, rather than the Soviet Union this time—was based on a flawed analysis of the data (Lynn and Salzman, 2010; Lowell and Salzman, 2007).

By 2007 when the report was issued, a booming economy made the claims of impending STEM failures less urgent than they had seemed following the dot-com crash earlier in the decade, when the crisis and failure reports began to proliferate (Teitelbaum, 2014). But a year later, the 2008 financial crisis put concerns about the US economy on center stage again.

In response to the financial crisis, an assemblage of science and industry advisers, along with many of the same authors of the 2007 RAGS report, offered in a 2010 follow-up the same argument of science and engineering declines in face of an ascendent China that portended an imminent threat to the nation like a "Category 5 hurricane." To the earlier report this one added further claims, again hyperbolic and fantastical, concluding the failure to respond to their first report could be seen as leading to outcomes that—quoting another 2001 report on which the same military contractor CEO served—were "second only to a weapon of mass destruction detonating in an American city ... " (National Academies, 2010, p. 66–67).

At the same time, President Obama assigned his President's Council of Advisors on Science and Technology (PCAST) the task of examining the future STEM needs in the economy. To bolster the mission of this group of science advisers, the President assembled a group of a dozen and a half industry executives and two labor representatives in an ad hoc Council on Jobs and Competitiveness, for which he tapped General Electric's CEO Jeff Immelt as chair. Their task was to formulate policies to address the causes of, and remedies to, the economic crisis and slow recovery. Remarkably, if consistent, the solution both councils identified was to increase the number of STEM graduates: the Jobs and Competitiveness council issued an interim report in June 2011 calling for 10,000 more engineers (Presidents Council on Jobs and Competitiveness, 2012). Shortly after that, the Science and Technology Advisors, in February 2012, called for one million more STEM graduates (Presidents Council of Advisors on Science and Technology, 2012).

Both of these proposals came a year after Apple's co-founder Steve Jobs told the president that Apple would have located its vast low-cost manufacturing operation, with 700,000 jobs, in the United States instead of China if only the company had been able to find enough US engineers to support its operations. And all these reports came on the heels of Obama's proclamation a year earlier that a new "Sputnik moment" had arrived, calling for more STEM workers to lead the economic recovery. Defying the evidence of vast numbers of STEM graduates without STEM jobs, the president, policy makers, the press and industry all united in their claim of STEM shortages. The shortage claim was once again used to advance political and policy goals of refocusing attention to failures of the education system rather than the financial system, and to renew calls for increases in lower paid guestworkers for the technology industries (Teitelbaum, 2014; Lynn and Salzman, 2011; Salzman, 2013).

STEM education and workforce development garners attention distinct from overall education and workforce development. In the post-war period, the strategic importance of science and engineering came from the obvious role it had in military weaponry as well as the general increase in the role of science and technology in the economy and everyday life. However, STEM policy was encumbered from the beginning with other political and policy objectives. As the focus of attention in response to broader anxieties—whether about international threats or domestic economic crises—STEM policy is seldom based on substantial empirical analysis. In particular, the persistent theme of STEM shortages is one of unfounded claims that often arise during a general period of economic or political turmoil; each and every time major reports on the STEM crisis have been issued, they have been found not to reflect reliable evidence.

Importantly, claims about STEM education and the workforce are often made with little conceptual clarity, and little empirical evidence, yet the STEM crisis remains a potent narrative that has wide appeal and broad applications in advancing policy in education and workforce development. It seems to matter not that, in more than half a century of STEM education and workforce shortage claims, the supporting evidence has never withstood careful examination; in fact, although "STEM" is a term widely used, it has no consistent or coherent definition.

What is STEM anyway? Conceptual and definitional issues

For all the political importance ascribed to STEM, it has come to describe a rather wide range of disciplines and occupations, inconsistently used from one study or policy to another, and all lacking a logically or empirically consistent or defensible definition. Does STEM denote fields of study? Occupations? Or a body of knowledge that is applied across any number of occupations? Indeed, all of these permutations are used in discussions and policymaking about STEM. The lack of a precise and agreed-upon definition of what counts as a STEM course, major, or occupation is a problem that, we find, would alter the evidence base that is used in many policy, funding, and education decisions. As it relates to education and workforce development, STEM is both a category of education and occupation. In this regard, there are two important sources of ambiguity in the definition of STEM.

The first of these is whether to include health majors and occupations under the heading of STEM. The first census of science and engineering (S&E) was developed by NSF for a series of indicators responding to Congress's request for an assessment of the nation's scientific and technical workforce. Because another US government agency—the National Institutes of Health (NIH)—is responsible for health and medicine, these fields are generally excluded from NSF's funding and data collection efforts. But as is obvious to even casual observers of education and workforce training, this distinction is more political than substantive. The curriculum for pre-medical studies overlaps significantly with the laboratory sciences of biology and chemistry, and health programs outside of premed have become increasingly reliant on mastery of scientific and technological content. The decision not to include graduates in health fields has an enormous impact on the reported size of a graduating STEM cohort or the STEM workforce (Oleson et al., 2014); including health graduates in STEM would increase the size of the STEM cohort by 20% or more. However, for the purpose of this analysis we follow nearly all other analyses of the STEM workforce and exclude health fields from our accounting of STEM education or the workforce.

A second problem relates to the definition of "technology"—the T in STEM. Programs of study in Computer Science and Information Technology may fit most neatly under the "technology" umbrella, but beyond this, what constitutes a technology program of study is unclear. In a rather remarkable expansion of the definition, the STEM label has been applied to HVAC installers and automotive technicians, and perhaps even includes janitors with the title "environmental engineer" (Rothwell, 2013). But apart from these ventures into empiricist absurdism, the technology workforce as part of the STEM classification refers to those with a college degree in a recognized technology field—computer science, manufacturing technology, etc.—or those in a professional occupation classified by the Bureau of Labor Statistics as technology fields such as computer programmers. When considering those with a technology degree, four-year and post-graduate degrees considered technology include computer science and engineering, while two-year Associates degrees also include machinists, repair technicians, etc. Health technicians such as radiology and EKG technicians, could be classified in either technology or health care. We developed a specific category of Health-tech for this group and do not include them in the STEM-technology grouping.

The estimates of demand for STEM workers and their potential supply, because of the diversity of the occupations, education, skills, and disciplines subsumed by the acronym, cannot be determined with any empirical or logical consistency or reliability. Workforce, education, and policy analysis thus needs to consider the specific disciplines and occupations that are relevant for a particular policy or program.

STEM demand and supply

To understand whether the supply of new workers is adequate depends on first identifying the number and trend of available jobs in STEM—demand—and the number of available STEM workers—supply. But since there isn't a standard or consistent definition of STEM, or of the specific qualifications needed for STEM jobs, discussions of STEM in the aggregate tend toward speculation and/or serving political purposes. For example, the more broadly one defines STEM, the larger the needed labor force, and thus the larger the potential to find a “shortage,” particularly—and paradoxically—when supply is not limited to a specific field of study. Estimates of the size of the STEM workforce vary dramatically based on whether these figures include healthcare occupations and “blue-collar” work involving machinery (e.g., advanced manufacturing), and on the decision whether to include jobs requiring less than a bachelor's degree (see below). One analysis found that estimates of the size of the US STEM workforce ranged from 5.4 million to over 26 million, depending on such operational choices (Oleson et al., 2014).

The largest category of US STEM workers, excluding health, is Information Technology (IT). In recent years, the IT industries have demand to fill about 50,000 new jobs per year (Zilberman and Ice, 2021) along with replacements for workers leaving these fields, with many of these jobs requiring less than a Bachelor's degree (see Fig. 1). In terms of supply, for the last eight academic years, the number of Bachelor's Degrees awarded in computer science awarded in the US has exceeded 50,000, and trended sharply upward, to over 95,000 in 2020. A similar trend of increased degree production is evident in engineering, where the number of new BAs increased from just over 75,000 in 2011 to over 129,000 in 2020. Demand for new engineers, however, is not expanding rapidly—that sector was only expected to have about 50,000 job openings per year, of which only 14,000 were new jobs and the balance replacements for retirements and those leaving the field (Torpey, 2018).

The technology industries pose a special case for estimating supply because the disciplinary background of that workforce is largely outside of computer science or IT fields, and even outside of STEM. Since nearly 30% of the IT workforce has less than a four-year college degree, and nearly half of those with a bachelor's degree did not major in computer science or engineering (see Figs. 1 and 2), the industry has a vast pool of potential workers to draw on for employment from the 470,000 STEM bachelors graduates, and 1.5 million non-STEM bachelors graduates, each year (U.S. Department of Education, 2020). The IT industry's very high turnover rates—reflecting its “burn and churn” employment practices that lead to low tenure—along with its preferences for hiring lower-cost guestworkers, may be factors that lead to the technology industry's stated demand as significantly higher than reflected in these projections (Lazonick et al., 2014; Salzman, 2016). Obviously IT occupations require a specific set of skills that may not be available in the population at large, but the rather modest needs of this industry for new hires, representing 8% of all industry annual workforce growth (Dubina et al., 2020), suggests the IT industry should be able to address its supply needs with no more difficulty than other STEM industries that require much higher levels of formal education and training (see Fig. 1).

Fig. 3 Major fields of bachelor's graduates. Authors' tabulations based on: Digest of Education Statistics, 2015–2019 NCES Chapter 3.

Global STEM supply and domestic labor markets

The supply of domestic and global graduates varies quite dramatically by discipline and degree level, as do the labor markets for each occupation. Traditional calculations that examine just national education and labor markets without consideration of global flows do not accurately reflect STEM workforce supply and demand. Nor do analyses that examine these factors aggregated across disciplines or occupations provide much insight. In the US, the STEM supply and labor markets are structured to a significant degree by several guestworker policies enacted primarily for the technology industries and for computer science and engineering degrees, but also include the other STEM fields. These are guestworker work permits and visas known as the Optional Practical Training

Fig. 4 Global student flows and graduate supply. Authors' tabulations based on: National Center for Education Statistics, Integrated Postsecondary Education Data System (IPEDS), 2018.

(OPT) student work permit, H-1B nonimmigrant high skill visa, and a few other categories such as the L-1 non-immigrant intra-company transfer visa. These visas are estimated to supply a guestworker labor pool equal to between one-half to two-thirds of all new entrants to the technology industries (Salzman, 2016; Rosenthal, 2021).

The supply of potential guestworkers, college graduates who qualify for a nonimmigrant visa or work permit, varies by degree level and field. As shown in Fig. 4, foreign students are a small share of bachelors graduates but comprise over half of Masters graduates in computer science, engineering and mathematics. Student flows into technology master's degree programs have increased dramatically in recent years. This reflects a change in US visa policy that vastly expanded the workforce entry options for foreign students. The two major routes into the workforce for foreign students during the 1990s and early 2000s had been the H-1B visa and, with much longer waits, permanent resident status known as the green card. Congress proposed legislation to expand these programs, in part fueled by the industry-driven shortage reports discussed earlier, but ultimately failed when the guestworker legislation was merged with broader immigration legislation (although part of the immigration bill, the H-1B visa and related visas and work authorizations, such as the OPT work authorization for the student F visa, are guest worker, nonimmigrant visas but often and erroneously described as immigration visas in the media and research reports). Consequently, to provide the technology industry greater access to guestworkers, the existing one-year work permit for all foreign graduates, known as the Optional Practical Training (OPT) work authorization, was extended to 17 months in 2008 for STEM graduates and then, in 2016, the Obama administration extended it to two years for STEM graduates, in addition to the one-year OPT for all graduates, thus creating a three-year work permit for STEM graduates (Rosenthal, 2021).

This liberalizing of the OPT work permits in 2016 led to a dramatic increase in the numbers of foreign students obtaining three-year work permits, nearly doubling from 2016 to 2019, and increasing 13-fold from 2009 (Fig. 5). As found in an analysis by Bloomberg journalist Rachel Rosenthal in a recent in-depth analysis:

With no annual cap, the number of work authorizations exploded, to 203,000 in 2019 from 83,000 in 2008, according to Immigration and Customs Enforcement, which oversees many aspects of the program. About 411,000 people had documentation to work under OPT in 2019, not including another 126,000 from a related pre-graduation version of the program. The number of initial approvals for OPT has exceeded those for H-1B visas every year since 2015, according to data from US Citizenship and Immigration Services.

Rosenthal (2021).

Since there is no cap on the number of OPT work authorizations for the F visa, and it has none of the minimal wage or work protections of the H-1B visas—thus allowing employers to hire them as low as the federal minimum wage of \$7.25 per hour—these graduates became the preferred source of new entrants. Universities recognized the revenue potential of the OPT program because graduates from their two-year Masters programs could then easily enter the US labor market for three years while trying to obtain the more limited number of six-year H-1B visas. There was rapid expansion of Masters programs in computer science and engineering targeted exclusively or near exclusively to foreign students who would pay full tuition as the price of entering the US labor market.

Fig. 5 Growth rate of OPT Calculations by authors; based on U.S. Immigration and Customs Enforcement SEVIS data 2008=1.0/F visa, OPT; 2009=1.0/OPT STEM; OPT STEM lagged 1 year—Issued at expiration of first year OPT.

Although some colleges with established and reputable programs created or expanded their Masters programs for foreign students, the vast majority of graduate supply in technology fields came from unranked and low-ranked programs: “More than 70% of nonresident computer science master’s degrees awarded in 2018 came from unranked programs or those ranked 50 and lower by US News and World Report. Just 17% came from schools ranked in the top 25” (Rosenthal, 2021). In the past decade the colleges with the largest cohorts of Computer Science graduates were the unranked universities of Wilmington University, Central Missouri State University, Southern Arkansas University, and University of Cumberlands, where over 90% of the graduates were nonresident, or foreign students. Overall, more than two-thirds of nonresident computer science Masters graduates were in programs that could be considered exclusionary, that were 75%–100% nonresident students. This level of exclusionary programs is specific to Masters and PhD programs in computer science, some fields of engineering, and mathematics (see Fig. 4).

It was in this way that legislation provided the technology industry the opportunity to hire guestworkers at below market wages (Hira and Costa, 2021) which, in turn, shifted the demand away from domestic to nonresident foreign computer science and engineering graduates. In response, some universities shifted their business model to create programs that exclusively, or near-exclusively recruited full-tuition-paying nonresident foreign students. Justifying the expansion of these programs, with a large share coming from universities without a history or evident credentials in these fields, the STEM shortage narrative provided justification for the policies that sustained these programs (Rosenthal, 2021; Salzman, 2016). It is, thus, the intersection of government policies, global labor supplies and the opportunity for global labor arbitrage, along with entrepreneurial initiative by some universities that combine to structure one segment of the technology labor market different from other STEM labor markets or STEM education.

In summary, the evidence does not support the longstanding narratives of STEM shortages or the predictions of dramatic increases in demand that cannot be met by existing education institutions to provide the necessary supply (Salzman and Benderly, 2019; Lynn et al., 2018). Considering the political and industry functions of the STEM shortage narrative, and the development of a technology student and worker supply system that is exclusionary and draws on neither the high-talent capacity nor the potential diverse domestic pool of students and workers, the evidence suggests that the global education and employment systems inhibit full development of the STEM workforce potential in the nation.

Problems and problematics in the supply

Up to this point, we have raised questions about the definition of STEM and assessed claims of shortages of college-educated STEM workers. But beyond the issue of relative levels of supply and demand, there is of course a need for a trained or re-trained STEM workforce at both the Baccalaureate and sub-Baccalaureate level. It is thus necessary to assess obstacles to producing that supply of workers at both levels. This is particularly important when considering factors that can facilitate or hinder the development of a diverse STEM workforce and of drawing on the full potential within the nation’s population.

Sub-baccalaureate STEM credentials

While most discussions of STEM workforce development emphasize the supply of bachelor's degree graduates, it is important to recognize that over a quarter of all STEM occupations require less than a bachelor's degree (Fig. 1). Furthermore, nearly half of students who ultimately earn a bachelor's degree in the US spend at least some time at two-year postsecondary institutions, community colleges (NSC Research Center, 2017). And as concerns about diversity in the STEM labor force grow, it is important to consider that community colleges serve a more diverse population of students than any other sector of postsecondary education, and at much lower cost, providing greater access to lower-income students. Community colleges are thus a critical part of the STEM worker supply in the US (National Academy of Engineering and National Research Council, 2012), and any consideration of the STEM workforce needs to consider the role played by these two-year institutions.

Although community colleges are more diverse and provide greater access to education than four-year colleges, the completion rates are less than a third of those in four-year colleges. One study of students in the midwestern state of Ohio found that among students who begin their college careers at two-year institutions with intention to pursue a STEM major, only 14% remained in these fields at the time of their last enrollment, as compared to 43% of four-year college students (Bettinger, 2010). More recent figures indicate that 69% of entering STEM students at two-year colleges had either switched majors or left college altogether (Chen, 2013). Importantly, attrition rates from STEM fields are not dissimilar from non-STEM fields (Chen, 2013). But the difference in attrition rates between two- and four-year programs suggests that there may be differing supply problems in these two sectors.

Mathematics coursework and the supply of STEM graduates

Attrition from STEM majors is exacerbated by a curriculum structured to filter out students through mathematics courses that are not always necessary for the major. These are known as gateway courses because they can be a barrier to entry or continuation in a STEM pathway. At both the baccalaureate and sub-baccalaureate levels, entry or advancement in STEM fields of study is often contingent upon completion of mathematics courses. Indeed, such "service courses" for other fields of study are the primary function of mathematics departments in US colleges and universities. Our analyses of college transcripts indicate that STEM bachelor's degree earners completed about 17 mathematics credits—the equivalent of about five courses—compared to 8 credits among non-STEM majors. Among non-mathematics STEM majors, students in engineering (22 credits), physics (17 credits) and computer science (16 credits) earned the most math credits, with life sciences majors earning the fewest (9 credits). Notably, courses in college-level math and calculus in US colleges have uniquely high rates of failure and withdrawal, at 10% each, even when compared to other STEM courses (ranging from 3–5%), suggesting that mathematics courses play a gatekeeper role in STEM fields (Douglas and Salzman, 2020).

Mathematics remedial courses serve an additional gatekeeper role at the sub-baccalaureate level. Early in the last decade, nearly 60% of entering US community college students were assessed as needing remedial instruction in mathematics; almost double the one-third of students needing remedial instructions at baccalaureate institutions (Chen and Simone, 2016). Remedial placement decisions are typically made on the basis of one-off standardized tests, even as rates of misplacement with such tests were found to be fairly high (Scott-Clayton et al., 2014). Rather than remediating identified mathematics deficits, these courses lead to a high rate of students leaving without completing any degree (Attewell et al., 2006; Chen and Simone, 2016). Indeed, the pre-college level mathematics courses have the lowest success rates of any course type in US postsecondary education; nationally representative student transcript data shows that only 57% of pre-college mathematics course attempts end in success—grades of C or better—compared to 79% of college physics courses and 77% of college English courses (Douglas and Salzman, 2020).

Colleges, especially community colleges where the problem is most severe, have recognized this issue, and have begun to respond. Reforms to remedial mathematics policy have ranged from reforming curriculum and pedagogy to altering placement mechanisms, to modifying remediation requirements or eliminating them altogether (Rutschow et al., 2019). One element of curricular reform is to align required mathematics content with students' intended fields of study, based on the assumption that different degrees will require different types of mathematical knowledge. Generally, this has meant that students intending to pursue non-STEM degrees are placed on a track to take introductory statistics or other non-algebra courses, while STEM-intending students are placed on a track to take college algebra and/or calculus. In general, these reforms have succeeded in reducing rates of remedial mathematics placement and increasing college completion (Center for the Study of Social Policy, 2016). The gatekeeper function of mathematics courses, to "weed out" and reduce the pool of STEM-eligible students, is a longstanding practice but is not grounded in evidence for its utility pedagogically or occupationally. Research on mathematics use among US workers indicates that a very small proportion of US workers—even those in occupations that require college degrees—make regular use of mathematics beyond simple computation (Douglas and Attewell, 2017; Handel, 2016). Alignment of mathematics requirements with students' college-level coursework and eventual occupations needs to be carefully considered, especially if mathematics coursework requirements are limiting supply by increasing attrition from STEM majors or college dropout altogether.

STEM attrition and STEM attraction

The traditional—and often unexamined—narrative of STEM education in US higher education is the so-called "leaky pipeline." This narrative and supporting analyses are based on the observation that many students who begin their postsecondary education career in STEM fields change to non-STEM fields of study and ultimately graduate with a non-STEM degree. This pattern of STEM attrition has been the subject of many studies, with particular focus given to the departure of female and underrepresented minority students

(Seymour and Hewitt, 1997; Crisp et al., 2009; Hill et al., 2010; Chen, 2013). Consequently, policymakers in the US have focused attention on retention, of plugging leaks in the pipeline by creating programs to retain students in STEM majors.

The focus on retention is a positive development to the extent that it spurs cultural changes in STEM fields, such as reducing discrimination against particular groups of students or improving pedagogy. However, it is also important to recognize that college is a process of discovery about interests and abilities, and some amount of change in field should be expected and is beneficial. Indeed, nationally representative survey data indicate that one-third of four-year college students change their major at least once within their first three years, and that students leaving STEM majors is about as common as students leaving non-STEM majors (Leu, 2017). The focus on STEM education as a “pipeline” that has only unidirectional “leaks” has led to a truncated analysis that fails to consider the “late entrants” who discover and move into a STEM field after their first years following an initial period of exploration.

In our analysis of this flow of students from college entry to graduation, we find that although a large share of four-year college freshmen leave STEM majors and switch to non-STEM majors, there is a slightly larger number of students who begin as non-STEM or as undeclared majors and are “late entrants” into STEM (Salzman et al., 2021). This results in the graduating STEM cohort becoming larger than the starting STEM cohort. The assumption that STEM completion is predicated on initial entry into STEM is thus not supported by this evidence, nor by an assessment of the “STEM-potential” of the non-STEM student population.

The large pool of non-STEM students who are STEM-potential is indicated by the significant share of students with high levels of mathematics coursetaking: there are twice as many non-STEM college majors as STEM majors with mathematics course credit levels at the STEM population median level of mathematics course credits (Douglas and Salzman, 2020). That is, the non-STEM population is large and a significant share of them take mathematics at the same level of intensity as half of the STEM population. Some fields such as engineering are more difficult to enter late, but the vast majority of STEM fields do not require, nor does the typical major have STEM course intensity that is beyond the capacity of late entrants.

Moreover, if fostering flows in and out of STEM results in better matching, it may lead to better performance, satisfaction, and tenure in STEM careers. Currently, only a quarter to a third of STEM-degree holders work in a STEM occupation, and 15% of those in a STEM occupation with a four-year degree do not have any STEM degree (Kannankutty, 2007; Landivar, 2013). Instead of trying to “plug the leaks,” or making the boundary less permeable, a more productive approach might be analysis of STEM attraction rather than of just attrition, focusing instead on ways to improve the exploration and matching processes of students, of understanding both factors that account for retention/persistence and the factors that attract students into STEM fields.

Finally, we may want to reconsider the assumption that STEM development and national competitiveness are best served by strengthening a pipeline that has high throughput with minimal flows across disciplinary boundaries. For the STEM-eligible population, of the pool of high-performing students, it may be the loose coupling between STEM disciplines and STEM careers that provides the US some of its dynamism, innovativeness, and creativity. Steve Jobs famously said that Apple, among the world’s most highly valued companies, represents the intersection between technology and the humanities. Before Jobs, Edwin Land, co-founder of Polaroid and a developer of the nation’s first advanced aerial imaging technology as well as key advisor in the founding of NASA, had discussed the importance of “standing at the intersection of humanities and science.” The porous boundaries of the US education and career system should be seen as a strength that supports and fosters the creativity of cross-disciplinary meandering.

Conclusion

Simple notions about STEM workforce policy fuel debates about national competitiveness the world over. In the United States, the STEM crisis theme is a perennial policy favorite, appearing every few years as an urgent concern in the nation’s competition with whatever other nation is ascendant, or as the cause of whatever problem is ailing the domestic economy. And the solution is always the same: increase the supply of STEM workers through expanding STEM education. Time and again, serious and empirically grounded studies find little evidence of any systemic failures or an inability of market responses to address whatever supply is required to meet workforce needs. The large share of the STEM workforce that requires advanced college degrees means that supply responses will be lagged by two or three years, but in decades of study there is no evidence of a failure to create whatever supply employers are seeking to hire at market rates (Freeman, 1976; Salzman, 2013; Lynn et al., 2018; Freeman and Salzman, 2018). Instead, the motivating interests of STEM workforce shortages or failures are found to be attempts to shape policies for other goals, most recently to lower the cost of labor through global labor arbitrage facilitated by policies responding to manufactured crises (Berliner and Biddle, 1997; Teitelbaum, 2014).

Although the goal of increasing support of STEM education and workforce development would seem to benefit from this increased attention and funding, even if the motivation is misguided, the seemingly paradoxical effect of these policies is to undermine the nation’s, and the world’s STEM workforce development and capacity for innovation. The expansion of guestworker policies and programs has created a shadow STEM workforce system of universities that create Masters programs to supply the lower cost, guestworker labor market (Hira and Costa, 2021; Rosenthal, 2021; Salzman, 2016), and that allows employers to pay below market wages—in the case of H-1B workers, transferring \$3 billion to \$4 billion per year of forgone wages from employees to employers (Employment and Training Administration, 2021). This global labor arbitrage system leads firms to disinvest in their STEM workforces and rely, instead, on a low-cost, high-churn model of employment (Lazonick et al., 2014). To the extent that

the quality of the STEM workforce is a factor in endogenous growth models explaining national economic performance, this STEM disinvestment might be contributing to the recent productivity and innovation declines (Gordon, 2016).

STEM education and workforce development have suffered in the wake of policies purported to be strengthening them. Education and workforce policy are part of the overall political process that reflects conflicting goals and are too often supported by analyses and policy reports that are narrowly focused without the necessary historical context or detailed empirical specificity required to develop effective policy. A broader perspective on the political context of STEM crisis reports, and more rigorous research and analyses will better inform our understanding of the STEM fields and how to best strengthen them.

Introduction

Due in part to a worldwide concern over the number and diversity of students choosing to pursue careers in science, technology, engineering, and math (STEM), supporting and developing STEM interests in youth has become a high priority (e.g., [Moote et al., 2020](#); [Young et al., 2017](#)). Here we examine factors that are associated with family support for STEM career aspirations with a focus on “science,” particularly in light of recent work that has found associations between science capital, attitudes toward science, informal science learning, and “STEM” related outcomes, including interest and career aspirations ([Dou et al., 2019](#); [Moote et al., 2020](#); [Verdin, Godwin and Ross, 2018](#)). Many factors impact an individuals’ STEM interests and career aspirations, and families play a major role in the development of STEM interests (e.g., [Archer and DeWitt, 2016](#); [Jones et al., 2021](#); [Sha et al., 2016](#); [Silander et al., 2018](#)). In this chapter we examine how families influence the development of STEM interests and career aspirations of youth.

Before examining the role of the family in development of interests and aspirations, it is important to note that the concept of “family” is cultural and can vary between groups ([Tillman and Nam, 2008](#)). Formal definitions of family may not accurately reflect the various family types and may limit researchers’ “ability to fully examine patterns of exchange, support, and caregiving” ([Tillman and Nam, 2008](#), p. 368) that impact the members of the family. Further, different family members may play different roles in influencing aspirations. In interviews with college STEM students of color in the United States, [Rincón et al. \(2020\)](#) noted that mothers were especially influential in students’ decisions to pursue postsecondary education, fathers and siblings in their selection of STEM majors, and family members—including extended family such as aunts and uncles—and teachers in decisions to aspire to careers in STEM. When considering who is engaged in socializing children and who may impact their STEM interests and aspirations, it is important to think about who the family members may consider “family” to potentially include extended family as well as caregivers and unrelated individuals who are considered kin ([Yosso, 2005](#)).

The role of family in STEM aspirations

There is increasing evidence that an early introduction to science is important to support lifelong interests and exposure to potential careers (e.g., Cheryan et al., 2017; Jones et al., 2016). Even if a child does not seek to pursue a science career, enjoying science as a leisure activity, as well as being scientifically literate, equips individuals with a foundation for a science-rich life and the capacity to engage in decision-making in a world with an increasing science and technology focus (Sharon and Baram-Tsabari, 2020; Vahey et al., 2019). The development of science interests and aspirations tends to happen earlier for youth whose families are involved in the development of these interests (Dabney et al., 2013). However, family involvement in science has been shown to be related in many cases to the family's levels of science capital and family science habitus (Archer et al., 2015a; Claussen and Osborn, 2013; Sha et al., 2016).

Science capital

Science capital stems from Bourdieu's theory of social reproduction (Archer et al., 2015a). It refers to the economic, cultural, and social resources related to science to which a family has access (Archer et al., 2015a). This includes not only physical resources but also intangible resources such as relationships with people associated with science. Bourdieu (1986) described capital as representing the structure and function of the social world. He believed access to capital determines one's chance at being successful in one's endeavors.

Capital has three basic states: economic, social, and cultural (Fig. 1, Bourdieu, 1986). Economic capital is typically related to money and may also be seen as rights to property. Social capital is built of the social connections one has and is able to leverage. The cultural capital of an individual includes the knowledge, abilities, and cultural artifacts (such as books and art) an individual gains as part of their upbringing and education (Bourdieu, 1986). Science capital is a type of cultural and social capital that focuses on the value, knowledge, networks, and resources that individuals have related to science. Cultural capital is foundational for the development of habitus (Bourdieu, 1973; Chandler, 2013) which has also been proposed as an element of science capital (Archer et al., 2015a).

Fig. 1 Forms of capital. Adapted from Yosso (2005) and Archer and DeWitt (2016) as described in Ennes (2019).

Family science habitus

Habitus has been defined as a:

(s)ystem of lasting, transposable dispositions which, integrating past experiences, functions at every moment as a matrix of perceptions, appreciations, and actions and makes possible the achievement of infinitely diversified tasks, thanks to analogical transfers of schemes permitting the solution of similarly shaped problems (Bourdieu, 1977, p. 95).

From a social-psychology perspective, individuals have a series of internalized, cultural interests that are constantly competing with one another (Chandler, 2013). Cultural capital influences these field-specific interests (Chandler, 2013). A *field* is a socially structured environment that has its own set of rules and practices (Chandler, 2013). Science is one example of a field. The socialization of an individual into a particular field, such as science, at different points of their life will affect their habitus (Lizardo, 2004).

An individual's habitus is influenced by their experiences (Chandler, 2013; Dumais, 2002; McClelland, 1990), observations of others (McClelland, 1990), their place within society (or their family) and how they internalize that placement (Dumais, 2002; McClelland, 1990), race/ethnicity, gender, socioeconomic status (Archer et al., 2012), and capital (Reay, 1995). Habitus directs an individual's behaviors (Bourdieu, 1973), ways of speaking (Chandler, 2013; Silva, 2016), and belief systems (Archer and DeWitt, 2016; Silva, 2016). Additionally, habitus shapes what an individual believes is typical of who they are (Archer and DeWitt, 2016), as well as what is possible or acceptable for them to achieve in the future (Archer et al., 2012). Fig. 2 outlines several of the factors associated with habitus.

Archer et al. (2012) describe *family science habitus* as the way a family's capital (economic, social, and cultural) may influence the way the family thinks, identifies, values, talks about, and engages in science. These beliefs, values, and capital a family holds may influence the worldview that a child has regarding science (Archer et al., 2012). A family's habitus influences whether children are prepared to engage with the cultural capital of schools (Claussen and Osborne, 2013) or to engage in lifelong science habits and behaviors (Jones et al., 2016). A part of family science habitus, the types of experiences a family does or does not engage in, influences the science interests and career aspirations of the children (Jones et al., 2020). Fig. 3 summarizes the influences of parents and caregivers on the STEM interests of youth as outlined by Eccles (2015), with a focus on the role of capital and habitus as outlined in this chapter.

Parental support

Regardless of race or socioeconomic status, parents influence their children through their attitudes, encouragement, expectations, interests, aspirations, and role modeling (Dasgupta and Stout, 2014; Fisher and Padmawidjaja, 1999; Kiyama, 2010). They also affect their children's career aspirations through indirect pathways such as influencing their children's levels of self-efficacy, which influences children's career aspirations (Sawitri et al., 2015; Sha et al., 2016). Parental support allows children to explore careers and

Fig. 2 Factors influencing and influenced by habitus as described in Ennes (2019).

Fig. 3 Caregiver and parental influences on the STEM interests of youth as described by Eccles (2015).

may support their motivation and confidence in their career pursuits, leading to an increase in self-efficacy that helps them react positively to challenges to their career aspirations (Guan et al., 2016).

Parental support is important for all students, however, increasing this support for underrepresented youth may be particularly beneficial, especially as these students experience marginalization and discrimination in science contexts outside of the home (Cian et al., 2022; Kier and Blanchard, 2021). Researchers examining families from low socioeconomic contexts found that support from parents and caregivers may increase student science achievement for children (Perera, 2014). Additional research with African American students majoring in science at predominantly white universities said they persisted in their studies because their family communicated to them the value of education and held them to high standards (Nguyen et al., 2021; Russell and Atwater, 2005).

Early childhood experiences

There is increasing evidence that STEM interests and career aspirations begin early in childhood and not in the teen years, as was thought in earlier research (Auger et al., 2005; Moulton et al., 2018). As young children play, they develop an affinity for topics, such as science, that they find fun and engaging. Early engagement with science within the family comprises both family science habitus and contributes to the child's science capital.

Museums and informal STEM learning settings (e.g., after school centers, makerspaces, science media) have increasingly recognized the important role of the family in building STEM interests, and many of these centers offer play spaces related to STEM designed specifically for early childhood engagement (e.g., Museum of Life and Science in Durham, NC; Please Touch Museum in Philadelphia, PA). Although the recognition of early childhood experiences on STEM interests is growing among non-formal science centers, a survey of libraries and museums across Philadelphia showed that fewer than half identified working with young children as part of their mission and only a quarter considered it a "core service" (Sirinides et al., 2017). When parents do engage with their children in out-of-school settings, research suggests that parents support re-engagement in the science activities and help make connections of an activity with experiences and interests outside of the current activity (Pattison and Dierking, 2019).

Experiences with tools

Early childhood experiences also include opportunities beyond visiting informal STEM learning institutions. Recent research on the importance of family support of STEM interests found that parents and children have different perceptions about their access to science resources at home, with parents reporting having access to significantly more science tools in their home than their children (Ennes et al., 2022). This included tools such as rulers, measuring cups, and scales. Access to these types of foundational science tools are important for youth to develop their science process skills, and youth who do not have opportunities to develop these skills may be far behind their peers in their ability to engage in science inquiry lessons in school (Claussen and Osborne, 2013).

Experiences with tools were also seen as a vital part of a new model developed to explore the family influences on STEM aspirations (described below, [Jones et al., 2021](#)).

Families and STEM hobbies

The development of science interests in early childhood are often a result of family activities. In a study of nearly 3000 adult science hobbyists (defined as individuals engaging in science interests outside of work for pleasure), [Corin et al. \(2017\)](#) found that over half of the participants reported that their hobby began during their childhood. This study examined the development of ten different STEM hobby types. Corin et al. found that, across most of the hobby groups, the hobbyists reported their family had influenced their initial engagement with their hobby. Furthermore, the influence of the family was greater than that of friends, teachers, or other educators.

Similarly, [Jones et al. \(2019\)](#) examined the relationship between having a STEM hobby and selecting a STEM career. This study surveyed adult hobbyists and documented educational background, motivations to participate in a hobby, science identity, and influences of the hobby on career choice. Individuals who worked in STEM fields were more likely to report their career decisions were influenced by their family and their hobby interests and activities than those who did not work in STEM fields. When the STEM hobbyists who did not work in a STEM field were asked to rate factors that influenced that career decision, they reported their hobby interests began after their career decisions were made. Some of these non-STEM career hobbyists also indicated they felt they lacked the ability to pursue a career in the same area as their hobby.

Other research on the development of the interests of amateur astronomers and birders found that adult leisure interests began in childhood and were influenced by family members, having access to resources to explore the hobby (e.g., binoculars), and opportunities to experience the hobby ([Jones et al., 2017](#)). This study argued that the influences on life-long interests were driven by family members who provided support for interests, built self-efficacy for learning science, and supported motivation to continue to learn. The authors also suggest that these kinds of hobby groups provide individuals with a group identity and recognition that contributes to a sense of relatedness for STEM ([Jones et al., 2019](#)).

These studies suggest that leisure STEM activities during childhood, as well as participating in science alongside family members, teachers, and other educators influenced participants' STEM career decisions and leisure interests (see also [Dou and Cian, 2021](#)). In addition, this work showed that hobbyists who had STEM careers were more likely to report greater interests, ability, and identification with STEM subjects in school than those hobbyists who did not have a STEM career ([Jones et al., 2018](#)). These findings on hobbyists are congruent with career choice theory that maintains that career choice is influenced by interests (such as these hobby interests), outcome expectations, and self-efficacy ([Lent et al., 1994](#)). The role of leisure interests such as hobbies on the development of self-efficacy and identity for STEM has not been fully researched.

Gender differences

How parents engage their children in science can be influenced by the gender of the child (e.g., [Bhanot and Jovanovic, 2009](#); [Crowley et al., 2001](#); [Eccles, 2015](#); [Starr and Simpkins, 2021](#); [Tenenbaum and Leaper, 2003](#)). As suggested in [Fig. 3](#), [Eccles \(2015\)](#) theorized that a child's biological sex impacts the behaviors and beliefs of their parent or caregiver, which in turn affects the child's beliefs about what is possible and appropriate for them. Research on middle school students in the United States found that parents of boys were more likely to overestimate their child's ability in science than parents of girls ([Bhanot and Jovanovic, 2009](#)). This study found that when parents expressed that science was important for their daughter, the daughter valued science more; however, parent beliefs did not impact boys' value of science ([Bhanot and Jovanovic, 2009](#)). Additionally, the researchers found that when mothers had conversations with their daughters about the value of science careers and science interests, daughters valued science more highly. Other studies have found that parents explain more information to their sons when discussing science than they do with their daughters ([Crowley et al., 2001](#)). This body of work highlights the importance of family habitus that includes conversations around science particularly for families with girls.

A recent study examining the gender stereotypes that United States high school students held for math and science found that the beliefs students' held were positively correlated with their parent's beliefs ([Starr and Simpkins, 2021](#)). The parents in this study held fairly traditional beliefs that boys were better than girls in science, and by the time the students reached grade 11, the students' beliefs more closely reflected that of their parents. However, the gender stereotypes were fairly fluid between grades 9 and 11, suggesting that parents play a significant role in gender stereotypes and identities in high school ([Starr and Simpkins, 2021](#)). The authors concluded: "Parents' own gender stereotypes relate to their children's gender stereotypes and math/science identity, even as late as 11th grade" ([Starr and Simpkins, 2021](#), p. 293).

Another study in Australia found that parents of boys who were interested in science fields were more likely to have university aspirations for their children than parents of girls interested in science careers ([Lloyd et al., 2018](#)). The authors of this study suggested parents should pay close attention to the type of science role models they offer their children and that they themselves need to be aware of potential role models. The authors recommended that interventions not only target children but also parents so they can support their children's science interests regardless of gender ([Lloyd et al., 2018](#)). This supposition is supported by the work of [Archer et al. \(2013\)](#). In interviews with 10–14 year-old English girls and their parents, the researchers observed that parents expressed incongruity between "girliness" and interest in STEM careers, which were positioned in masculine terms, and that these perceptions were reflected in how their daughters thought of themselves in relation to science careers.

Among Latine youth, research has also suggested that the gender of the parent can also play a role in the ways youth, regardless of gender, engage in science related conversations and activities in the home. [Cian et al. \(2022\)](#) point to evidence suggesting that paternal caregivers tend to adopt stereotypical STEM “expert” like behaviors, such as providing factual knowledge to in-the-moment contexts, while maternal caregivers tend to identify and guide their children toward resources from which they could draw STEM related knowledge, such as by making relational connections to STEM professionals within their social networks.

Families from marginalized communities and underrepresented groups in STEM

Research across various contexts and geographies often presents family science capital as a characteristic of white or European, middle-to-upper class homes more so than the homes of children from marginalized groups in STEM fields. As alluded to earlier, Archer and colleagues’ ([Archer et al., 2015a](#)) conceptualization of science capital encompasses youths’ and families’ science related literacies, dispositions, perceptions of labor market value, practices, out-of-school participation, and social capital, which have exhibited repeated associations with demographic variables like race, ethnicity, and gender. For instance, in a study of black students and parents’ perceptions of science and science careers among children aged 10–14 in the United Kingdom, [Archer et al. \(2015b\)](#) noted that participants’ parents had less access to science material and science educational capital than their white counterparts whose children were more likely to access academic support programs, have family members who were highly educated, and understand how to navigate educational systems. While the authors noted that all families were optimistic about their children’s future, the support from black families was “often restricted to providing moral support, encouragement, guidance, and motivation, rather than subject expertise, social contacts, or expensive extracurricular activities” ([Archer et al., 2015b](#), p. 212) in relation to their participation in science activities.

Associations between family science capital and factors like race and ethnicity in particular do not always exhibit monolithic outcomes. [Wong’s \(2016\)](#) interviews with 46 students ages 11–14 revealed nuances in these relationships and the complexity of the influence of family capital in developing and maintaining career aspirations. For instance, black Caribbean boys in the study were among the few to express interest in careers as research scientists and that interest appeared to be sustained by their family capital such as science toys, books, and trips to museums. But, their interest was classified as “minimal,” meaning they actually mentioned more non-science aspirations than science aspirations and Wong noted that it was unclear where the science aspirations ranked among the students’ other career interests. Still, these students reported below-average grades in science but still held science-related career aspirations, suggesting a sustaining influence of family capital. [Jones et al.’s \(2020\)](#) validation study of a science capital survey with middle school students ($N = 889$) exhibited high correlations (0.67) with youths’ expectancy values, which included their science-related self-concepts and perceptions of how others recognize them in science, as well with youths’ perceptions of the value their families place on science and science careers. Yet, resonating with [Wong’s \(2016\)](#) study, their instrument exhibited only partial scalar invariance with regard to participants’ gender and ethnic scalar invariance, suggesting that across these demographic factors, subgroups of individuals differ in how they interpret and respond to one or more of the science capital survey items.

[Nguyen et al.’s \(2021\)](#) interviews with black women STEM students attending Historically Black Colleges or Universities (HBCUs) illustrated how parents capitalized on everyday opportunities to engage children with STEM, which “gave their children access to understanding of the importance of STEM in daily life” (p. 890). In a survey study of Hispanic youths attending a Hispanic Serving Institution (HSI), [Dou and Cian \(2022\)](#) similarly reported on the contributive effect of everyday science talk with close family members on STEM aspirations. While these two studies describe parent-child interactions that were conducive to STEM pursuits, others have noted that families communicate support for STEM aspirations non-verbally. [Avraamidou \(2022\)](#) relates the story of Zehra, a physics instructor who grew up in Turkey before being educated in the United States and moving to Europe to work. Zehra’s family communicated support for her aspirations by deciding not to oppose them, which was unusual for a girl in their cultural context.

Many of the findings presented in these and similar studies complement [Gonsalves et al. \(2021\)](#) claim that “students’ accumulation of science capital is not sufficient for engagement in postsecondary science” (p. 30). Researchers have further identified resources that families use to support child STEM aspirations that are unique to marginalized and underrepresented families. [Rodriguez et al. \(2021\)](#) observed that Latina college students attending a Predominantly White Institution (PWI) in the United States invoked *familismo*, or “a strong attachment to nuclear and extended family” (p. 1778) as a motivator for their aspirations. Students discussed feeling that their accomplishments were shared by their families, a sense of support their families communicated when they felt challenged, and a willingness to acquire a career that enabled them to provide for their families. [Yosso \(2005\)](#) introduced the concept of Community Cultural Wealth (CCW) by looking at cultural capital with a critical race theory (CRT) lens. CCW highlights six forms of capital: aspirational, or the capacity to aspire in spite of obstacles; linguistic, or fluency in multiple languages or dialects; familial, or shared cultural knowledge and history; navigational, or capacity to find one’s way through complex social systems; and resistant, or the acquisition of skills through facing inequity ([Fig. 1](#)). Empirical research has further developed these ideas. For instance, in a phenomenological study of 38 black and Latinx STEM college students in the United States, [McGee and Bentley \(2017\)](#) noted that their participants were driven to STEM careers by an “equity ethic” such that they viewed STEM careers as opportunities to serve marginalized communities and disrupt inequities—an ethic that the authors noted could be contributed to their belonging to collectivist cultures that are “likely to place a higher priority on group goals, needs, beliefs, and expectations” (p. 6) and have experienced more “violence or adversity” (p. 7, citing [Vollhardt, 2009](#), p. 53).

Another area that has received considerable attention is the family capital that is unique to families with immigration histories. Erel (2010) used a case study of three migrant women to illustrate how, rather than translocating capital from one country to another—which may or may not have value in the migrant location—new forms of capital are forged through the migration process and existing forms of capital are renegotiated for fit in the new context. Further research has supported this suggestion. A student in a study of interactions between immigrant fathers and their children in a family workshop related his father's ability to help him in science to his father's past work in construction and "on the land" (Allestaht-Snider et al., 2020), evidencing both this student's respect for his father's former career and its relationship to science and a broader concept of what could constitute as a career that supplied family science capital. Latine college students interviewed in a study by Herrera and Kovats Sánchez (2022) associated their desire to pursue STEM careers with their parents' immigration stories. However, in interviews with second-generation migrant college STEM students in the United States, Cian et al. (2022) noted that students' dismissal of their mothers' STEM expertise was related to their mothers' abandonment of a STEM career that they had held in their migrant country. Several researchers have noted that the value migrant families place on STEM careers relates to their children's science-related outcomes. Gokpinar and Reiss' (2016) study of Turkish immigrant students highlights how parental attitudes toward science contribute to children's science interests and attainment even across families with "very similar [socioeconomic] and parental, ethnic and sociological backgrounds" (p. 1294).

Modeling and predicting family influences on STEM career aspirations

Researchers have recently begun to model the role that the family plays in the development of career aspirations and interests in science. These models are based on various theoretical frameworks that have been used to assess the STEM career aspirations of youth.

Science identity

Several of these frameworks examine career aspirations from identity or self-concept perspectives. As described by Hazari et al. (2010), science identity is made up of an individual's interest (their desire to learn about science), the recognition they receive from others, their performance (an individual's belief about their ability to perform specific tasks), and their competence (an individual's belief about their ability to understand science). Students may have confidence in their academic abilities but still feel unwelcome in STEM spaces because of individual characteristics such as gender or race/ethnicity. If an environment is not purposefully inclusive, individuals can feel like they do not see themselves as working in that environment or that they lack the requisite identity to participate. STEM engagement and academic achievement can be affected when students do not identify with the STEM disciplines such as science (Kang, 2019; Singh et al., 2002). Studies have shown participation in informal STEM experiences, often with family, develops a student's scientific identity and promotes their interest as a future STEM professional (Adams and Gupta, 2013; Dasgupta and Stout, 2014; Dou et al., 2019; Goff et al., 2020). In addition to educational settings, informal experiences predicted participants' STEM identity. Simple activities such as talking with friends and family about science are predictive of STEM identity in college (Dou et al., 2019). In a study with nearly 16,000 participants examining how STEM identity, experience, and career aspirations relate, Dou et al. (2019) found that participants' probability of choosing a STEM profession increased by 85% for every one-point higher on their STEM identity scale.

Science self-concept

Closely related to identity and overlapping with self-efficacy, academic self-concept is defined as a person's perceptions about themselves and their knowledge competence in academic situations (Bong and Skaalvik, 2003; Byrne, 1984; Shavelson and Bolus, 1982; Wigfield and Karpachian, 1991). Awareness of one's academic ability is directly related to how confident the student feels in pursuing a STEM career. Studies have shown that students who also experience science outside of school with their families have a stronger positive self-perception within STEM (Kang et al., 2019). Students with positive academic self-concept reported higher persistence, goal-setting, intrinsic motivation, and STEM career aspirations (Bong and Skaalvik, 2003).

Academic self-concept is often associated with specific school subjects. In a study looking at low-income communities across the United States, Kang et al. (2019) found self-concept in science is a strong predictor of girls' STEM-related career aspirations. Self-concept in mathematics and science self-concept are regarded as significant indicators of a student's professional pursuit across all STEM fields (Bong and Skaalvik, 2003; Kang et al., 2019; Sax et al., 2015). Overall, a student's academic self-concept, coupled with a personal interest in STEM, increases their probability of choosing a career within STEM (Adams and Gupta, 2013).

Social cognitive career theory

One of the earliest theories applied to career aspirations is that of social cognitive career theory (SCCT), proposed by Lent et al. (1994). This theory suggests that beliefs related to self-efficacy, outcome expectations, and goal-related beliefs influence career decisions. This theory has been applied in a variety of studies in different contexts (e.g., Byars-Winston and Rogers, 2019; Dutta et al.,

2015). SCCT has been used to predict the role of interests, social supports (e.g., family), social barriers, self-efficacy, and outcome expectations (Lent et al., 2008) on career aspirations.

Expectancy-value theory

Building on similar expectation-related constructs that are included in SCCT, expectancy value theory (EVT) has emerged as a useful and valid tool to predict achievement-related choices such as career selection (Eccles and Wigfield, 2020). This comprehensive theory allows researchers to account for individual factors such as aptitude, gender, race/ethnicity, prior experiences, and cultural variables such as family demographics and social role systems as well as between-person variables such as perceptions of socializer's beliefs, social roles, affective reactions and memories, as well as self-schemata (identity and self-concept). According to this model, these in-person and between-person variables contribute to an individual's subjective task value, or the perception of the attainment value, utility value, and costs for making an achievement-related choice such as a career choice. This model has become widely applied and validated in studies across different disciplines and contexts (e.g., Ball et al., 2016; Fielding-Wells, 2017; Watkinson et al., 2005).

Modeling STEM career aspirations

Recent research on the influence of the family on students' career aspirations (Jones et al., 2021, 2020) applied constructs of science capital and habitus with factors of expectancy value theory. Using a national sample and structural equation modeling, Jones et al. (2021) found science capital factors (Tool Access, STEM Experiences, and access to STEM practitioners) were influential in predicting students' Science Achievement Value and students' perceptions of Family Science Achievement Value (the degree students thought their families valued science) (Fig. 4).

This model further showed that Family Science Achievement Value along with Science Achievement Value are associated with Future Science Task Value (i.e., career aspirations). The study examined how those out-of-school variables such as access to tools and knowing people who worked in STEM fields influenced students' perceptions of the value of science for their future. Models such as these described above allow us to predict and identify career choice variables and to design new forms of intervention that can support students' budding interests in science and other related fields.

Assessing family influence and STEM career aspirations

In this final section we describe a selection of instruments that specifically assess familial influences on STEM career aspirations. The following surveys were strategically chosen as they are all validated measures.

ASPIRES

The ASPIRES survey (Archer and DeWitt, 2013) was validated and was developed to improve researchers' understanding of youth science career aspirations. Youth in the United Kingdom completed Likert scale survey items on a variety of evaluative topics including, but not limited to, aspirations in science, attitudes toward school science, images of scientists, and parental expectations. The target population for this survey is young people ages 10–14.

Fig. 4 Structural equation model depicting factors that predict Future Science Task Value. Adapted from Jones et al. (2021).

NextGen Scientist Survey

The NextGen Scientist Survey is a tool that measures the accessibility of factors related to science capital and habitus (Jones et al., 2021, 2020). More specifically, the aspects of the survey include science experiences, science achievement value, perceptions of family science achievement value, and future science task value (Jones et al., 2021). The NextGen Scientist Survey has been validated for upper elementary students (age 8–10; Jones et al., 2022) and middle grades (age 11–13; Jones et al., 2021, 2021) in the United States. The validation of the parent version of the survey is forthcoming.

S-STEM

The S-STEM survey (Unfried et al., 2015) measures attitudes toward and career interest in STEM. The survey has two versions that have been validated for upper elementary students (age 8–10) as well as for middle and high school (age 11–18). The survey is divided into four sections that assesses STEM attitudes, confidence, performance expectations, career aspirations, and access to STEM professionals.

TOSRA

The Test of Science-Related Attitudes (TOSRA; Fraser, 1978) assesses students' (secondary school students, age 12–15) attitudes toward science. TOSRA is composed of several domains which include enjoyment of science lessons, leisure interest in science, and career interest in science, just to name a few. It can be used among both students and caregivers (Fraser, 1981).

Conclusion

As noted in this chapter, research has shown that youth do not develop science interests or STEM career aspirations on their own. Rather, they form it in a family context. Families play an important role in helping their children develop their ideas of what they could, should, or might do in the future as it relates to science and STEM careers (Archer et al., 2012). This is done through early childhood experiences, out-of school family activities, engagement with tools, and exposure to STEM hobbies. These experiences have been shown to influence the self-efficacy (e.g., Bandura, 1978), identity (e.g., Hazari et al., 2010), and academic self-concept (e.g., Bong and Skaalvik, 2003) of youth related to science. Research is emerging that shows that by engaging children in interventions that also involve the whole family, the child's developing science interests and career aspirations are supported (Ennes et al., under review; Ennes and Jones, 2021). These interventions can be examined using several theoretical frameworks including social cognitive career theory (e.g., Lent et al., 1994) and expectancy-value theory (Eccles and Wigfield, 2020). Recently, new models have also been developed to better understand the family influences on STEM career aspirations (e.g., Jones et al., 2021). Families are responsible for the early introduction of children to science which can support lifelong interests and the development of career aspirations (e.g., Cheryan et al., 2017; Jones et al., 2016). Given the increasing dependency of society on science and technology, children, families, and the broader society can benefit from a focus on family engagement in science as these efforts enhance STEM literacy and support formal and informal interests (Sharon and Baram-Tsabari, 2020; Vahey et al., 2019).

Introduction

In the US alone STEM jobs are predicted to grow by 8.8% between 2017 and 2029 (Zilberman and Ice, 2021). Similarly, in Australia, between 2014 and 2019, employment in STEM occupations grew by 19.7% which is 1.9 times higher than other occupational groups (Department of Education, Skills and Employment, 2020). This expected growth is offset by skills shortages in STEM areas, leading to employer difficulties in filling positions (Department of Education, Skills and Employment, 2020). Difficulties in attracting interest in STEM is further exacerbated by lower participation rates in some STEM areas (for example, computing and engineering) for females and particular cultural and ethnic groups (Fry et al., 2021).

The participation rates of females in STEM higher education and in some STEM careers consistently lags behind that of males. In Australia women made up less than a quarter of students studying in STEM fields in 2019 and 5 years after graduation males with a STEM qualification were 1.8 times more likely to be working in a STEM-qualified occupation compared to their female peers (Department of Industry, 2021). Globally there are more women than men enrolled in higher education, but these women are less likely to enroll in STEM fields, particularly in engineering, computer science and physics (The World Bank, 2021).

Aspirations for future study and careers begin forming in childhood and trajectories are often solidified in early adolescence (Berger et al., 2020). It is important, therefore, to understand the factors that can support or undermine aspirations in the STEM fields during the secondary school years. Some factors are related to individuals and their concept of themselves as STEM learners, while others sit at the school or community levels, interacting with individual factors to enable or disable the development of strong STEM aspirations throughout the school years.

Formation of STEM aspirations

The STEM acronym represents a broad range of career options, with some research studies focusing solely on careers in science, technology, engineering and mathematics (Holmes et al., 2018; Luo et al., 2021), while others include careers in related fields such as health care and medicine (Sadler et al., 2012; Sáinz and Müller, 2018). Similarly, some studies focus on attitudes toward STEM subjects and skills generally during school (Atabey and Topcu, 2021) while others examine particular STEM subjects and their influence on STEM aspirations (Ardies et al., 2015; Blotnick et al., 2018). This wide variation in the interpretation of what STEM represents presents a level of complexity when trying to disentangle the relevant factors at play in shaping aspirations for STEM careers.

Aspirations for STEM careers are seeded during the school years. In a longitudinal study (2012–2015) of 6492 students in Years 3–12 in Australia, STEM aspirations were examined in relation to a broad range of student and school level factors (Holmes et al., 2018). The study was shaped by a comprehensive theoretical framework drawing on notions of human, social, cultural and economic capital and operationalized at the student and the school level. In this study STEM careers were defined as those requiring a tertiary qualification in science, technology, engineering or mathematics and of the total sample 894 (13.8%) students expressed a desire for this type of career. However, these aspirations were unevenly distributed in number, and by gender, across the four STEM domains with 553 (47% female) students expressing interest in a science career, 207 (6% female) in a technology career, 396 (91% female) in engineering and only 8 (33% female) in a mathematics career. Male students were three times more likely to aspire to a STEM career than females, but aspirations for STEM careers did increase in the older cohorts of students compared to the younger cohorts. Students in the highest quartile for prior achievement in reading and numeracy were also more likely to aspire to STEM careers. Remarkably, student socio-economic status or Indigenous status were not significant variables in the presence of other predictors. However, the study did find that students with a parent in a STEM occupation were more likely to aspire to a STEM career, as were those in the higher quartiles for cultural capital (a measure based on how frequently students attended cultural events, galleries, museums and libraries) (Holmes et al., 2018).

In the US, ethnicity has emerged as a factor related to STEM aspirations with Asian students aspiring to STEM in greater proportions than other racial groups (Edwin et al., 2019). This finding was reinforced by a large study of US ninth grade students, which indicated that STEM aspirations were influenced by race, gender, socioeconomic status, math interest and science self-efficacy (Mau and Li, 2018). The authors found that being male, white, having a higher SES, having greater parental educational expectations, higher maths interest and science self-efficacy was related to aspirations for STEM careers. Female student aspirations were found to be hindered by a lack of confidence, unfair treatment and discrimination, financial pressures and biased stereotypes (Mau and Li, 2018).

STEM aspirations are influenced by factors that can be broadly categorized as being related to the student at the individual, family, school or broader community levels. At the individual level, student demographic factors and their attitudes to STEM subjects have been examined in relation to their aspirations (Ahmed and Mudrey, 2019). At the family level, the influence of parents is recognized as being an important influential factor in the formation of young peoples' aspirations for STEM careers (Lloyd et al., 2018). At the school level various practices can have an influence on student attitudes to STEM (Reinhold et al., 2018) and at the broader community level there has been a strong focus on stereotypes that are prevalent in relation to the study of STEM subjects and STEM careers (Makarova et al., 2019). The influence of these proximal and distal factors will be discussed in the following sections.

Factors related to STEM aspirations

Individual factors

Numerous studies have examined student attitudes to STEM careers and STEM subjects at the secondary school level. Many of these studies have drawn on existing datasets generated by international testing schemes such as PISA (Program for International Student Assessment). Using PISA data a US study of 5611 15 year olds found that students who enjoy science and perceive it as useful were more likely to aspire to STEM careers (Ahmed and Mudrey, 2019). Similarly, using PISA data from the United Arab Emirates, Cairns and Dickson (2021) found that STEM career aspirations for both genders were related to enjoyment of science, science self-efficacy, interest in science and instrumental motivation. It matters, therefore, how students feel about science while at school, with more positive attitudes being related to the development of aspirations for future STEM engagement.

Of the STEM subjects, attitudes toward, and participation in mathematics has been consistently found to be related to STEM aspirations (Sax et al., 2015; Wang et al., 2017). In a large Canadian study of 1448 students in grades 7–9, those with low mathematics self-efficacy were found to have declining interest in STEM careers over time (Blotnick et al., 2018). In a Finnish study of elementary students' motivation across three subjects (Finnish languages, science and mathematics), those who were "math-motivated" were more strongly associated with aspirations for STEM occupations (Oppermann et al., 2021). In addition to attitudes toward mathematics, the level of mathematics studied in school has also been found to have a major influence on STEM aspirations. In a very large ($n = 650,000$) Israeli study over 15 years, the choice of more advanced levels of mathematics in school, rather than the level of success in those levels, was found to be the best predictor of choosing STEM as a major in secondary school, completing a STEM bachelor's degree and succeeding in that degree, and of making a STEM career choice (Kohen and Nitzan, 2022). Helping students to aspire to higher levels in mathematics during school and keeping them motivated and confident in mathematics, therefore, can better prepare them to aspire to STEM careers. However, by contrast, there is evidence that the relationship between mathematics interest and careers in the health area is not as strong as for other STEM careers (Wiebe et al., 2018).

STEM aspirations are also influenced by attitudes toward science as a school subject (Mau and Li, 2018; Sahin and Waxman, 2021). In a large study of almost 3000 middle school students in California, students who were "activated" toward science were more likely to have a greater affinity toward STEM careers (Dorph et al., 2018). In this study science learning activation was operationalized a multi-faceted construct including affinity, fascination, valuing, competency beliefs and scientific sensibility. Interestingly, the valuing of science was correlated more with career aspirations in the fields of technology and engineering, than careers in mathematics and science (Dorph et al., 2018). While attitudes to science generally are important for STEM aspirations, the nature of that science interest is also important, as it has also been found that those interested in physics at the start of secondary school had the greatest retention in STEM study throughout school (Sadler et al., 2012). Also, differences have been found in the factors related to intention to study the various science disciplines such as biology, chemistry and physics. In a study of 125 adolescent girls, the intention to study biology was predicted by self-efficacy in biology and social support from teachers. In this study, intentions to study chemistry and physics were predicted by self-efficacy in each subject respectively, but also by the degree to which the students endorsed a growth mindset (Mackenzie et al., 2021).

Other influences

Student attitudes are strongly related to the formation of STEM aspirations and are often the key determinant in whether a student pursues STEM study and ultimately a STEM career. These attitudes, however, are influenced by a wide range of factors including family, schooling, and community attitudes.

At the family level there is evidence that student STEM aspirations are positively related to the STEM occupation of parents (Holmes et al., 2018) and that fathers are more likely to have a STEM qualification than mothers (Department of Industry, 2021). The influence of family members could also be dependent on context, with mothers found to be more influential on student

aspirations for STEM in Turkey when compared to the United States (Bahar and Adiguzel, 2016). The level of education of mothers has also been found to be related to STEM aspirations in a Spanish study of almost 800 students (Sáinz and Müller, 2018). In this study, boys with mothers with intermediate education levels were more likely to aspire to STEM careers in architecture and technology, and girls with mothers with high levels of education were more likely to aspire to STEM-related health careers. In a study of Australian students, students aspiring to STEM careers were typically higher achieving than their peers and more than 90% of their parents had aspirations for them to attend university (Lloyd et al., 2018). Parents have also been found to be influential in the subject choices that students make at school (Sahin and Waxman, 2021) which is important given that subject choice in school has been found to be related to retention in STEM in the long term (Kohen and Nitzan, 2022).

Schools have a significant impact on the formation of aspirations for students' future study and career choices. Students in particular types of schools have been found to hold STEM aspirations, particularly if they were male, in a private school with high socioeconomic status and with high mathematics self-efficacy (Ketenci et al., 2020). A further study using PISA data from 55 countries confirmed the relative advantage of students in private schools in developing STEM aspirations, although this advantage was stronger for males than females (Mann et al., 2015).

It is not only school type that is related to student STEM aspirations but also the initiatives that schools offer to encourage STEM participation and build self-efficacy in STEM subjects, with many of these initiatives focusing on supporting female aspirations in STEM. Some success has been found through the use of STEM career scenarios and active engagement with science experts and scientific practices (Drymiotou et al., 2021). A 9 week intervention designed to improve career decision making self-efficacy and STEM self-efficacy was found to increase these outcome measures with a sample of 88 high school girls (Falco and Summers, 2019). However, there is also evidence that improving motivation and attitudes to STEM may not be sufficient to ensure STEM participation for girls. An intervention designed to highlight the opportunity to fulfill communal goals in mathematics and science did increase interest in STEM careers for high school girls (Fuesting et al., 2017). Girls have been shown to be more motivated by altruistic goals than boys in expressing interest in future careers (Gore et al., 2015).

STEM career aspirations can also be impacted when students engage with informal STEM learning or higher education institutions. A large scale ($n > 15,000$) retrospective study of college students found that campus visits during their schooling, when they involved meetings with college professors, increased their odds of expressing STEM career aspirations (Kitchen et al., 2018, 2020). A summer learning experience focused on connecting STEM to students' everyday lives with authentic hands-on experiences, exposing them to a broad range of STEM careers and highlighting how STEM careers can help improve lives, was found to increase interest in STEM in middle school students (Maiorca et al., 2021) as did a summer STEM camp (Vela et al., 2020) and other out-of-school activities (Donmez, 2021).

Beyond educational institutions it is important to recognize the impact of cultural norms and stereotypes on the formation of STEM aspirations, particularly for females. While self-efficacy in STEM subjects has been consistently demonstrated to be predictive of STEM career interest, there is evidence that negative STEM stereotypes can impact on mathematics and science self-efficacy (Gariott et al., 2017; Luo et al., 2021). However, it is not only stereotypical beliefs about STEM careers that can impact on STEM aspirations. School subjects also have varying degree of masculinity associated with them. In a study involving 1364 Swiss secondary students, mathematics was considered to be the most masculine subject, followed by physics and chemistry respectively (Makarova et al., 2019). These perceptions of STEM subjects as gendered to varying degrees has the potential to influence the subject choices of students at key points during their education.

The research on the development of STEM aspirations paints a complex picture of interacting variables that act to support or discourage students toward STEM study and careers. It is clear that STEM self-efficacy and achievement in STEM subjects is important, but attitudinal variables such as enjoyment, interest in, and valuing of STEM are also significant for shaping students' futures in STEM fields. Also important is the degree to which students have accurate information about the broad range of STEM occupations and the veracity of common STEM stereotypes.

Many of the influences discussed in this chapter were outlined in a comprehensive review article examining the factors that are important in study choice and career development in STEM for 8–16 year olds (van Tuijl and van der Molen, 2016). The authors recommend three, potentially malleable, factors that could form the basis for action to improve STEM participation beyond schooling. Firstly, parents', teachers' and children's knowledge of the STEM field needs to be improved, including by allowing children to experience STEM activities that are relevant to their lives, interests and abilities. Also, the authors point to the need to make parents aware of the extent to which children circumscribe STEM aspirations early in their schooling, and the need to ensure that students have knowledge of the vast range of STEM careers. Secondly, the study points to the need to be aware of and to counter the affective aspects of STEM, largely influenced by STEM stereotypes that reinforce STEM as a "male- and things-oriented" field. Thirdly, the review identifies the importance of individual factors such as self-efficacy and ability beliefs, highlighting the need to turn entity beliefs (that ability is fixed) into incremental beliefs (that competencies can be developed over time) in STEM subjects (van Tuijl and van der Molen, 2016). These three foci have been confirmed in the research included in this chapter and provides a useful framework for those concerned with improving STEM outcomes for a broader range of students.

Theoretical perspectives

There are a range of theoretical perspectives employed by researchers to understand the complexities that surround the formation of aspirations for particular types of careers. Those most commonly employed include Social Cognitive Career Theory

(SCCT), developed by [Lent et al. \(1994\)](#), Expectancy-Value Theory, developed by [Eccles et al. \(1983\)](#) and the Theory of Circumscription and Compromise ([Gottfredson, 1981](#)).

Social Cognitive Career Theory ([Lent et al., 1994](#)) aims to capture how career development occurs by examining the connections between cognitive and interpersonal factors, alongside self-directed and externally imposed influences. The theory has its origins in Albert Bandura's general social cognitive theory which emphasized the relationship between "self-referent thought and social processes in guiding human behavior" ([Lent et al., 1994](#), p. 258). The theory posits that the personal determinants of career development can be represented by three variables: self-efficacy, outcome expectations and personal goals. These individual variables are then situated with contextual and experiential factors such as gender, culture, support systems and barriers ([Lent et al., 1994](#)). Furthermore students' learning experiences play a "pivotal role as a mediator between personal backgrounds and socio-cognitive mechanisms in SCCT" ([Kang and Keinonen, 2017](#), p. 1672).

The SCCT model has informed the development of a career-oriented learning environments as a means of assisting with career decision making ([Drymiotou et al., 2021](#)). The contextual features that were effective in the development of STEM aspirations were found to be learning experiences which: actively involved students in problem solving; established connections with authentic workplace environments; and included interactions with STEM experts ([Drymiotou et al., 2021](#)). SCCT links self-efficacy and career interest and therefore, learning experiences designed to improve student self-efficacy have been found to impact on students' interests and future aspirations, alongside the influence of parents and families ([Murcia et al., 2020](#); [Maiorca et al., 2021](#); [Sahin and Waxman, 2021](#)).

Expectancy-Value Theory (EVT) is another theoretical framework commonly employed in studies of student aspirations and career interest. The theory suggests that individuals show motivation to pursue particular choices depending on their expectation of achieving that outcome and the value that they place on that outcome ([Wille et al., 2020](#)). An individual's expectancy for success is closely linked to their self-concept ([Eccles and Wigfield, 2002](#)) and their value beliefs can be understood as a combination of intrinsic value, attainment value, utility value and associated costs ([Wille et al., 2020](#)). EVT constructs have been demonstrated to predict student achievement and career interests in STEM ([Parker et al., 2014](#); [Wang et al., 2017](#)).

Gottfredson's theory of circumscription and compromise focuses on the development of aspirations through a consideration of the compatibility of one's self-concept with a given occupation ([Bittinger et al., 2021](#)). Gottfredson perceived self-concept to include the beliefs that people hold about themselves, their interests and their place in society ([Cochran et al., 2011](#)). The theory proposes that children, as they move into adolescence, circumscribe their potential future aspirations based on social factors such as the gendered perceptions of certain careers and the social prestige of those careers ([Gottfredson, 1981](#); [Cochran et al., 2011](#)). Gendered perceptions of STEM careers are well established and are reflected in the statistics presented at the beginning of this chapter.

The three theories discussed in this section have similarities in the ways that they explain how individuals develop aspirations and make career choices. They each recognize the interplay between individuals and the social worlds that they inhabit, whether it be the influence of parents and families or the impact of school learning experiences on the choices made by individuals. In this way, each provides an appropriate lens through which to view the formation of aspirations and to ensure that efforts to increase STEM aspirations are suitably targeted toward factors that can make a difference, particularly for under-represented groups.

Recommendations for further research

The research included in this chapter reveals a largely consistent picture of the factors that are important for the development of aspirations for further STEM study and STEM careers. It is clear that self-efficacy in STEM subjects, particularly for mathematics, is vital if students are to continue to study STEM and that interest, enjoyment and valuing of STEM subjects is also significant. Beyond the individual, however, the influence of family and dominant societal norms and stereotypes, also play a role in student choices as they plan for their futures. The ongoing perceived "maleness" of some STEM subjects, such as physics for example, and of STEM careers in technology and engineering, continues to work against the many efforts that are being made to encourage more girls and young women to persist in studying STEM subjects.

The STEM acronym can be both a blessing and a curse for addressing the issues that remain. While it has been useful to consider the science, technology, engineering, and mathematics disciplines as a cohesive group, allowing for significant attention to be drawn to the STEM sector as a whole, it is clear that there are substantial differences between the S, T, E and M disciplines. Similarly, there are differences within disciplines, for example in science, between biology, chemistry, and physics. Future research into the development and support for STEM aspirations should take a more fine-grained approach, carefully delineating between STEM disciplines and sub-disciplines so that programs designed to address under-representation can be better targeted. Not all STEM disciplines are affected by gendered stereotypes, for example, and mathematics, while vitally important in some STEM disciplines is less important in others. If we are to increase interest and participation in STEM generally, while addressing the need to improve the under-representation of particular groups of students, then our research base also needs to diversify to better understand the inequities across the STEM landscape and the most promising ways to address them.

Introduction

Self-efficacy can be defined as people's "beliefs in their capabilities to produce desired effects by their own actions" (Bandura, 1997, p. vii). That is, self-efficacy is not one's awareness about existing skills or capabilities, it is the *belief* of what one can do with those skills and capabilities. Self-efficacy beliefs are specific to a task within a specific domain (e.g., Pajares, 2005). This means that self-efficacy is *not* a personality trait. Personality involves general and stable patterns of thinking, feeling and behaving; in contrast, self-efficacy can be specific to a particular skill or domain. Indeed, measures of self-efficacy for specific domains can be more predictive than general measures of self-efficacy (e.g., Bandura, 1997; Maddux, 1995). Because self-efficacy is a belief, it can also be relatively independent of objective performance, being more consistent with the subject's own *interpretation* of that performance.

Self-efficacy is a construct about the self

Self-efficacy is related to, but different from, other psychological constructs about the self, such as self-esteem and self-concept. *Self-esteem* is a global evaluation of the self that involves strong emotional components (e.g., self-like; Gist and Mitchell, 1992), whereas *self-concept* is related to domain-related perceptions about the self that can include evaluative and/or emotional components (e.g., "I am good in science"). In contrast, *self-efficacy* is specific to a task or goal (e.g., "I will do good in the taxonomy test"), does not involve a self-evaluation or self-like component, and is independent of others' capabilities (Bong and Skaalvik, 2003). Self-efficacy is strongly associated with self-concept, but they do not necessarily vary together. For example, high self-efficacy for different science tasks may contribute to a high science self-concept, but an individual can have a high science self-concept and low self-efficacy related to a particular task or assignment. Self-efficacy is more predictive of performance than self-concept (Britner and Pajares, 2006), possibly because it modulates both self-regulation (self-monitoring and assessment; Zimmerman, 2000) and cognitive engagement (Pintrich, 2003; Zimmerman, 2000) during task completion. In a similar way, self-efficacy (associated with performance) may vary with self-esteem (associated with self-worth), but they can also be dissociable. Self-esteem can be categorized as a trait-level construct, so one can have high overall self-esteem while simultaneously having low self-efficacy for a particular task (Richardson et al., 2012).

Development of self-efficacy

Sources of self-efficacy

According to Bandura (1977), self-efficacy beliefs are derived from four primary sources:

- Mastery experience* refers to the outcomes of previous task performance. These outcomes can act as reinforcers or punishers of self-efficacy, with successful outcome attainment increasing self-efficacy, and failures to attain outcome lowering it.
- Vicarious experience* refers to observations of others performing a task. Characteristics of the actor, and whether the individual can identify with the actor, influence the impact of these vicarious experiences.
- Social persuasion* refers to the feedback of other individuals (particularly those who are influential to the individual) regarding one's performance.
- Physiological and emotional reactions* refer to the individual's interpretation of the physiological reactions that are triggered by the task (e.g., sweaty palms, fast heart rate, "butterflies" in the stomach).

Mastery experience and physiological/emotional reactions constitute intrapersonal sources of self-efficacy, whereas vicarious experience and social persuasion constitute interpersonal sources of self-efficacy. Intrapersonal and interpersonal sources can interact to determine self-efficacy. However, despite strong correlations among the four sources of self-efficacy listed above (mastery experience, vicarious experience, social persuasion, and physiological reactions; e.g., Klassen, 2004), their relative contribution to self-efficacy is not equal. For example, mastery experience is a more robust determinant of self-efficacy than vicarious experiences, which are in general stronger determinants of self-efficacy than social persuasion. However, social persuasion can be a very robust determinant if the person providing the feedback is a person of authority, highly trusted, or considered an expert. Furthermore, mastery experience influences self-efficacy only if successes and failures are attributed to one's own behavior (Maddux, 2012). Mastery experience tends to have a linear relationship with self-efficacy (the more experiences with successful completion of a task, the higher the self-efficacy), whereas physiological reactions may not have such a linear relationship with self-efficacy (e.g., moderate stress can improve performance but high levels of stress usually impair it).

Even though the sources of self-efficacy are presented as individual factors, each of these sources is not experienced in isolation. For example, if a student is taking a test, the mastery experience is likely to be accompanied by physiological and emotional reactions (e.g., anxiety). The student is also likely to see others attempting or completing the same test, and will receive feedback from the teacher regarding performance in the test. Thus, self-efficacy will not be determined by a single source; rather, it is the integration and interpretation of these four sources of information that will eventually determine self-beliefs.

There is also a reciprocal relationship between performance and self-efficacy. Students with high levels of self-efficacy set more challenging goals for themselves, and achievement of those goals can boost self-efficacy (conversely, failure to attain goals can decrease self-efficacy). Furthermore, successes that result from overcoming challenges may have a stronger impact on self-efficacy than successes that are easily won. Because self-efficacy is a belief, mastery itself does not lead to strong self-efficacy; rather, it is the interpretation of the task in terms of context, previously held beliefs, perceived difficulty, and perceived effort that determines its impact on self-efficacy. This means that if the individual does not have prior experience with the task or their own abilities, vicarious learning or social persuasion may become more relevant than mastery experience (Britner and Pajares, 2006).

Reciprocal determinism and self-efficacy

Bandura (e.g., 1978) suggested that behavior influences and is influenced by personal factors and the social environment. In this *reciprocal determinism* framework, behavior (e.g., performance, skills, practices) is determined by the individual (e.g., self-efficacy, cognitive abilities, attitudes) and the environment (e.g., imposed environments, selected environments, constructed environments). For example, a student who does not feel confident about his or her capacity to pass a math course (individual) may not turn in an assignment (behavior) leading to a negative comment from the teacher (environment), which may lead to the student feeling even less confident about his or her capacity to pass the math course (see Fig. 1).

Fig. 1 Reciprocal determinism. Behavior (e.g., a student turning in an assignment for a class) is determined by individual (e.g., student's self-efficacy) and environmental (e.g., teacher's response to the student) factors. In turn, the consequences of behavior can impact individual and environmental factors. See text for details.

Measurement issues

Several scales have been developed to measure the four sources of self-efficacy (see **Sources of self-efficacy**; e.g., Britner and Pajares, 2006; Hampton, 1998; Lent et al., 1991), but they have proven unreliable to assess the impact of interpersonal sources of self-efficacy (vicarious experiences and social persuasion; Ahn et al., 2017; Usher, 2009). Vicarious experience measures typically rely on questions such as, “Seeing adults do well in math pushes me to do better,” which effectively assess both the vicarious experience and the resulting self-belief (Ahn et al., 2017). Similarly, social persuasion measures typically include questions such as, “My classmates said that I understood everything taught in class,” which not only assesses the impact of feedback but also corroborate self-efficacy information (Ahn et al., 2017). Thus, self-reports of interpersonal sources of self-efficacy can be biased by personal self-efficacy beliefs (Ahn et al., 2017; Zander et al., 2020). Recently, Zander et al. (2020) suggested that information from the subjects’ social environment can be used to gain a more reliable estimate of the impact of interpersonal sources of self-efficacy. For example, rather than assessing vicarious experiences by asking a student whether seeing adults do well makes the student want to do better, they proposed to ask students who would they select as a role model, and then assess the model’s competence-related status (i.e., the model’s grade in the course). Similarly, rather than assessing social persuasion by asking a student whether her classmates think she understood a particular topic, Zander et al. proposed asking the classmates whether they would approach the student to ask her questions about the class topic. Unfortunately, these measures have their own limitations. For example, intentions to ask for help do not necessarily reflect actual requests for help, thus decreasing the predictive value of the measure.

Academic self-efficacy

Self-efficacy as a predictor of academic performance

When considering academic performance, self-efficacy can be divided into *performance self-efficacy* (beliefs about one’s capacity derived from past experiences) and *academic self-efficacy* (beliefs about one’s capacity derived from perceived competencies). Performance self-efficacy is useful when encountering familiar tasks, whereas academic self-efficacy is useful when encountering unfamiliar tasks, for which past experiences provide little information (Richardson et al., 2012).

Self-efficacy develops partially based on feedback regarding performance (Fig. 1). For students, performance feedback usually takes the form of grades, and as feedback accumulates (more grades are accrued in a particular subject), self-efficacy stabilizes. Beliefs about competency are important to set both short-term (e.g., passing an exam) and long-term (e.g., passing a course) academic goals, and influence the interpretation of mismatches between goals and performance. These mismatches can be interpreted in different manners based upon levels of self-efficacy. For example, a student with high self-efficacy obtaining a lower grade (performance) than desired (goal) could interpret the mismatch as a result of behavioral factors (e.g., not studying hard enough), whereas a student with low self-efficacy could interpret it as a result of individual factors (e.g., lack of capacity). This different interpretation would then strengthen or weaken self-efficacy (respectively), leading to differential goal setting and effort to attain those goals. Achieving a long-term goal requires attainment of many short-term goals; thus, self-efficacy can be continuously strengthened or weakened on the path to obtaining those goals (Rittmayer and Beier, 2009).

Students’ beliefs about their competency are highly predictive of their grade point average (GPA; Pajares and Miller, 1995). In turn, grades are powerful determinants of self-efficacy, depending on whether the student interprets the grade obtained as a success (“I studied hard and got a B!”) or a failure (“I got a B but I should have gotten an A”). Academic successes and failures may have different impacts on self-efficacy. Good grades seem to be less influential for the development of self-efficacy than bad grades; that is, good grades will not strengthen self-efficacy as much as bad grades will weaken self-efficacy (Crocker et al., 2003). Similarly, negative or discouraging appraisals can weaken self-efficacy more than positive or encouraging appraisals can strengthen self-efficacy (Britner and Pajares, 2006). The type of feedback that is delivered in the academic environment also appears to have a critical role in academic achievement: Constructive feedback (e.g., references to the accuracy of the work completed) has a more positive impact on self-efficacy than feedback about deficiencies (e.g., references to the things missed in the work completed; Britner and Pajares, 2006).

Academic self-efficacy and academic self-regulation

Self-efficacy is an essential component of self-regulation (e.g., Barone et al., 1997), the processes that allow an individual to decide how to best implement his or her efforts. Self-regulation depends on individuals setting goals for performance, which can motivate and guide action, and on self-evaluations of such performance, which result in emotional responses that can enhance or disrupt self-regulation. Self-efficacy beliefs determine the extent to which the goals set are challenging, the choice of activities to be performed to attain those goals, and how discrepancies between goals and performance are interpreted (Maddux, 2012). Pintrich (2004) suggested that self-regulation is related to the constructs of goal orientation, approach goals, academic intrinsic motivation, and academic self-efficacy. Pintrich’s model can be assessed with the Motivated Strategies for Learning Questionnaire (MSLQ), which assesses the use of cognitive strategies such as rehearsal, organization, critical thinking, and some aspects of metacognition. Academic self-efficacy would be directly related to effort regulation, which determines persistence in the face of challenges (effort regulation can be viewed as similar to achievement motivation; Richardson et al., 2012). Thus, self-efficacy is intrinsically related to

goal-setting and attainment, the choice of behaviors that will be used to pursue those goals, the self-evaluation of the outcomes of one's efforts, and persistence toward those goals.

Self-efficacy in STEM

Within any given domain, self-efficacy is a powerful predictor of motivation, persistence, and task performance (Bandura and Locke, 2003). When it comes to the domain of science, engineering, technology, and mathematics (STEM), self-efficacy is a better predictor of task performance than past performance in objective assessments, such as tests and assignments (Bandura, 1986; Bandura and Locke, 2003; Larson et al., 2015). Persistence in STEM fields also shows a robust positive association with self-efficacy (Shaw and Barbuti, 2010). Starting in middle school, science self-efficacy is strongly associated with science achievement (Britner and Pajares, 2006), and self-efficacy scores become one of the most reliable predictors of achievement and engagement with science activities in high school (Lau and Roeser, 2002) and college students (Gwilliam and Betz, 2001).

Self-efficacy scores are not only positively correlated to science and math grades (Britner and Pajares, 2006), they are also positively correlated to effort, persistence, engagement and interest in science (Schunk and Pajares, 2002; Zimmerman, 2000). The reciprocal relationship between performance and self-efficacy is mirrored by a reciprocal relationship between interest and self-efficacy. Successful performance in a task leads to increased interest and future pursuit of that task, often at a more challenging level. Indeed, high self-efficacy leads to engagement and persistence in challenging tasks (Komarraju and Nadler, 2013; Pajares, 1996) and self-efficacy is more strongly associated to interest than actual skill or ability (Bandura, e.g., 1991). For example, successful completion of a basic math class may boost interest in math and pursuit of an intermediate math class; indeed, individuals with high self-efficacy tend to choose challenging classes and not view the challenge as a threat (Watt, 2006).

Importantly, as is the case for other forms of self-efficacy, academic self-efficacy is not general to a domain, but specific to tasks within that domain. For example, performance in solving math problems is more strongly associated with students' confidence in their capacity to solve math problems than with their confidence in their capacity to perform math-related tasks or succeed in math-related courses, whereas confidence to succeed in math-related courses was more strongly associated with students' choice of math majors than with their confidence in solving math problems or performing math-related tasks (Pajares and Miller, 1995). However, overall math self-efficacy is not only a strong predictor of math performance, but also a predictor of choice of science-related courses and careers (Lent et al., 1991).

Gender differences in self-efficacy and STEM achievement

It is well known that women and certain racial/ethnic groups are severely underrepresented in STEM careers (National Science Board, 2020). Because self-efficacy beliefs are robust predictors of STEM success, it is not surprising that self-efficacy is a focus for educators who wish to increase engagement and performance in STEM. Among middle schoolers, female students have higher science self-efficacy scores (and hence, higher science grades) than male students (Britner and Pajares, 2001). Although these gender differences are not evident among high schoolers (Lau and Roeser, 2002), the opposite pattern begins to emerge and solidify as students transition to tertiary education. Gender differences in self-efficacy seem to be discipline specific, with self-efficacy for males being higher than for females in "hard" STEM disciplines such as physics, chemistry, mathematics, and engineering, equivalent across genders in life sciences such as biology, and higher for females than males in non-STEM disciplines such as English (Whitcomb et al., 2020). Thus, underrepresentation of women in some STEM disciplines is associated with low self-efficacy scores for those disciplines.

In 2014–2015, women obtained 58.01% of bachelor's (BS) degrees in the biosciences and 54.58% of BS degrees in the social sciences. In contrast, women obtained only 19.8%, 18.1%, and 41.7% of BS degrees in engineering, computer science, and mathematics, respectively (National Center for Science and Engineering Statistics, 2017). Notably, while the gender gap in math achievement has grown smaller, females are still overall less likely to choose STEM careers than males (e.g., Hyde, 2014; Zander et al., 2020). This is a paradox, because math is a foundational discipline for all other STEM fields, and achievement and interest should be expected to vary together.

Traditionally, women have been seen as innately less capable of excelling in math, an assumption that has been challenged by the progressively closing gender gap in math achievement (e.g., Hyde, 2014). Social gender stereotypes are a clear determinant of math and STEM choice, with gender gaps being almost nonexistent in countries in which these stereotypes are less prominent (Glazer, 2019). Gender biases create *stereotype threats*, in which individuals fear confirming the stereotypes that the social group has about them. Biases and stereotypes are environmental factors that can powerfully impact math and STEM self-efficacy in women. As mentioned above, self-efficacy is usually a better predictor of performance than past objective evaluations (Larson et al., 2015; Pajares, 1996). Thus, even if female students receive math grades that are equivalent to those of male students, they may be more likely to hold beliefs about insufficient math abilities than male students (e.g., Else-Quest et al., 2013). Thus, female students do not lack the capacity to do STEM; rather, they lack the belief that they are able to do STEM (Rittmayer and Beier, 2009). (Note that the lack of belief in one's capacity could be viewed as associated to the so-called *imposter syndrome*, in which individuals who are high achieving doubt their capacities and feel like a "fraud" for their accomplishments).

Mastery experiences increase academic self-efficacy for both male and female students, but it seems that mastery experiences (intrapersonal sources) are most important for male students, whereas social persuasion and vicarious learning (interpersonal

sources) appear to be most important for female students (Butz and Usher, 2015; Sawtelle et al., 2012; Usher and Pajares, 2008). Mentors and role models can be powerful sources of social persuasion, and experiences with role models who belong to one's same gender and/or racial group increase their persuasive value. Observation of *female* role models in STEM is an especially robust determinant of STEM self-efficacy for female students (Seymour, 1995; Zeldin and Pajares, 2000). However, any mentorship by a STEM expert can have a powerful impact on students' STEM self-efficacy because such mentors provide encouragement and recognition (Carlone and Johnson, 2007; Stout et al., 2011) and provide intellectual discussions that can boost self-efficacy through mastery performance (Rittmayer and Beier, 2009).

Male and female students may also engage in different cognitive strategies to interpret successes and failures that may determine how their academic beliefs are impacted by mastery experience. Male students are more likely than female students to engage in *self-enhancement* (positive views of the self that are not consistent with performance; Kurman, 2004), and these enhanced views of the self can in turn enhance self-efficacy beliefs for male students, but not their female counterparts.

Educational strategies to develop and strengthen STEM self-efficacy

Use of mastery experiences

Educational programs can be used to help students develop and strengthen their beliefs in their own capacities. Self-efficacy can be strengthened by providing students with *mastery experiences* through interventions such as active and hands-on learning (Kuchynka et al., 2021), structured goal-setting and encouragement to develop self-regulation strategies (e.g., Dunlap, 2005), and proximal goal setting with increasing-difficulty tasks that ensure continuous success (e.g., Luzzo et al., 1999). At a practical level, this means that activities that encourage the development of self-regulation, are age- and ability-appropriate to ensure and encourage success, and which can be broken down into small, short-term goals should be beneficial for the development of self-efficacy (Rittmayer and Beier, 2009). Other strategies may include providing students with immediate feedback related to their performance in order to adjust their self-efficacy beliefs to their actual mastery performance. Considering that girls tend to have lower STEM self-efficacy and self-enhance less than boys, immediate feedback regarding good performance may allow them to incorporate a successful experience more effectively than receiving delayed feedback (Zander et al., 2020).

Use of vicarious learning

Vicarious learning experiences are especially relevant for young women, and their impact is usually mediated by whether the students can identify with the model (i.e., if they view themselves as similar to the model; Zeldin and Pajares, 2000), and whether the vicarious experiences are provided along with other interventions (e.g., mastery experiences; Luzzo et al., 1999). Formal and informal environments can provide a variety of vicarious STEM experiences, including interactions with STEM professionals in structured and unstructured situations, mentoring by STEM professionals, shadowing STEM professionals at work, audiovisual materials that expose students to STEM professionals' life experiences, and workshops and summer or after-school camps (American Association of University Women, 2004). Female students appear to benefit most from mentoring if inequalities in STEM achievement are described explicitly as part of interventions that expose them to female STEM role models (Weisgram and Bigler, 2007). Possibly, explicit discussion of gender inequalities in STEM allows students to re-evaluate and adjust their beliefs about their own STEM capacities. At a practical level, group work in which a peer with high ability to complete the task, and interactions with role models (e.g., older students and STEM professionals) with whom the students can identify (both in terms of race and/or gender) should encourage the development of self-efficacy (Rittmayer and Beier, 2009). This is especially important for female students.

Use of social persuasion

Social persuasion can be used to support other interventions aimed at increasing STEM self-efficacy. Positive feedback from individuals who are relevant to the student can dramatically impact their beliefs about their own abilities. Parents' expectations about their children's performance in academic tasks can be reliable predictors of the child's objective performance (Vekiri and Cronaki, 2008) and choice of STEM careers (Bleeker and Jacobs, 2004). Positive feedback can increase the impact of mastery experiences, especially if students receive support to interpret performance failures as opportunities for learning (rather than threats to self-esteem; Yeager and Dweck, 2012; Zander et al., 2020). Constructive feedback (e.g., comments about strategies for improvement) has a more positive impact on self-efficacy than feedback about what has not yet been accomplished (e.g., comments about deficiencies; Britner and Pajares, 2006). At a practical level, feedback should be framed in positive terms, encourage students to view failures as part of the learning process, provide information that allows students and relevant others (e.g., parents) to become involved in the learning process, as well as encourage participation in extra-curricular activities in which positive feedback is likely (Rittmayer and Beier, 2009). Importantly, feedback should also be *realistic*; that is, it should be based on the student's actual skills and capacities. Unrealistic feedback can create unrealistic expectations, lead students to set goals that are not attainable, and which can possibly result in performance failures. Even if such unrealistic feedback is positive, it can have negative consequences for self-efficacy.

Other strategies

Some researchers have proposed the use of imaginal experiences in situations in which performing the task or observing others performing the task is not possible. This could be achieved either by imagining situations based on prior experiences, or by having

another individual guide the imaginal experience (Williams, 1995). However, the impact of such imagined experiences on the development of self-efficacy beliefs is likely to be minor.

Conclusion

Academic performance appears to be closely related to self-efficacy beliefs. High levels of academic self-efficacy are strongly associated with the use of self-regulation strategies, high levels of cognitive effort, and persistence to achieve increasingly more challenging academic goals. Academic self-efficacy is a strong predictor of grades, especially in science subjects. Feedback about performance (grades) can strengthen or weaken self-efficacy, as mastery experiences are one of its most powerful sources. Negative performance evaluations seem to outweigh positive performance evaluations, suggesting that educational interventions that present material in an incremental fashion or in a way that guarantees mastery should strengthen self-efficacy. This should create a positive feedback cycle: Self-efficacy is related to the choice of behaviors used to pursue academic goals, self-evaluation of performance, and persistence toward those goals. That is, self-efficacy is relevant for both self-regulation of academic behaviors and metacognition about one's performance.

STEM Self-efficacy is a better predictor of STEM performance than the results of previous objective evaluations (e.g., scholastic assessments such as tests and assignments). STEM self-efficacy is also associated with motivation, interest, and persistence in STEM disciplines, suggesting that interventions that increase self-efficacy should also increase interest and persistence in STEM. Indeed, differences in self-efficacy appear to be one of the reasons for differences in the desire to pursue STEM careers and STEM achievement among male and female students, despite equivalent objective capacity (i.e., grades). Interventions that increase mastery experiences do not appear to be enough to encourage female students to persist in STEM; rather, female students appear to be more sensitive to the impact of vicarious experiences and social persuasion, especially if those vicarious experiences are by a model who resembles them (i.e., a female), and if the persuasive messages are provided by someone highly relevant to them (e.g., a respected STEM professional, parents).

Importantly, although self-efficacy has been reviewed here as an isolated factor associated to academic motivation and achievement, self-efficacy interacts with many other cognitive and emotional factors that determine academic motivation. Strategies to incorporate self-efficacy into educational strategies should take advantage of such interactions to foster their effectiveness.

Introduction

What did you want to be when you grew up? Did your career dreams come true? Did your parents help you on your journey toward becoming what you wanted to be? Were your extended family, schools, or other external community, state, and government resources helpful in supporting your interests?

Like many children growing up, my dream was to become a veterinarian. This dream was somewhat logical for a child growing up in an agricultural community in the deep south. Family and neighbors nurtured my love of animals as best they could. They drilled me on different breeds of companion animals and livestock, posed questions about other species, requested help identifying unusual characteristics of miscellaneous critters they would come across in our rural environment, invited me over to watch their companion animals and livestock births/hatchings, and even organized an opportunity for me to shadow a local veterinarian, which made me feel more connected to veterinary medicine than ever before. These early learning experiences shaped my views about science. However, being raised by my grandparents, who had only sixth and eighth-grade educations, foretold limited options for parlaying my love of animals into a career in veterinary medicine.

Although they did not have formal knowledge of veterinary medicine, my grandparents relied on our community for resources to help support my interests. In addition, they ensured that my teachers were aware of my interests and abilities and taught me the importance of believing in myself. But negative perceptions about what a Black boy from rural Alabama was capable of were powerful, so my primary interest in STEM became more secondary. Signals received in more formal learning environments told me I was not the type of child who should reasonably expect to become a veterinarian because I was neither White nor naturally talented at math. I am Black and struggle with math. My passion for veterinary medicine became less intense with each year due to the enormous burden of not fitting the mold and lacking knowledge and resources. My personal experience illustrates the tension between position, identity, and resources. It lends credence to the notion that STEM participation requires an interconnected ecosystem ripe with opportunities for formal and informal inclusive learning and support.

Today, I am not a veterinarian, but I am a scientist. Over the past seven years, my collaborative interdisciplinary teams have been awarded several federal grants from the National Science Foundation to support STEM learning, performance, and persistence for diverse students. So, as a researcher, I know the tools necessary for solidifying learners' STEM intentions and commitment. As an underrepresented minority (URM), I know barriers to educational persistence erode STEM interest and engagement. My experience as a researcher and a URM impacts my understanding of factors that promote STEM career awareness and participation among underserved populations and guides how the teams I work with approach designing and implementing early interventions that integrate and assess technologies for increasing STEM participation.

To close gaps in American competitiveness in the global STEM market, to increase representation of racial and ethnic minorities, and to encourage more women to participate, we must nurture STEM learning ecosystems in ways that empower young learners with STEM interests. To help you better understand how we can reframe STEM as a more viable career option for URM students, I provide recommendations based on lessons learned from my research. Hopefully, this provides a lens through which others can better understand factors that position underserved students for success in STEM and lead toward STEM careers.

Explanations for the lack of URM representation in STEM education and workforce linked with inadequate preparatory STEM education offer limited insights into relevant psychosocial factors that undergird URM interest in STEM participation. Here, I surmise that tending to students' learning ecologies provides inroads toward renegotiating longstanding science stereotypes and that both formal and informal experiences inside and outside the classroom can shift URM students' identities and position them for transformative career opportunities.

Positioning a diverse STEM workforce for STEM careers

Current trends indicate URM STEM participation drops perniciously from early k-12 education throughout postsecondary education due mainly to pervasive science stereotypes, which results in URM students having difficulty developing identities as scientists. Changing dominant cultural narratives about underrepresented minorities in STEM will require early intervention and intentional tending to their learning ecologies, as STEM researchers link pervasive cultural stereotypes regarding science to early declines in STEM interest and participation (Totonchi et al., 2021; Dare and Roehrig, 2020; Battel et al., 2021). Premature disengagement from STEM also leads to disproportionate rates of URM students attriting from the STEM workforce pipeline (Almeda and Baker, 2020). STEM careers are lucrative and in high demand. However, current trends in government and private sector STEM workforce needs point to field and degree-specific disparities between available jobs and qualified employees. Positioning URM students for STEM careers requires systematic, intentional diversification of the STEM workforce to increase the available pool of eligible STEM employees ready to serve a global imperative driving STEM expansion and American competitiveness.

Much has been written about the dire need to increase STEM participation, and America clearly cannot afford to lose its competitive edge in the global STEM market. Expected growth in STEM employment necessitates expanding the pool of qualified STEM workers (Langdon et al., 2011; Carnevale et al., 2011). Between May 2009 and May 2015, there was a 10.5% increase in STEM occupations (Fayer et al., 2017), and STEM occupations are expected to grow by 8.9% from 2014 to 2024 as compared to 6.4% for non-STEM jobs (Noonan, 2017). This growth equates to roughly 1.5 million job openings for selected STEM occupations between 2012 and 2022 (Vilorio, 2014). Considering increases in STEM job creation, statistics from the National Science Board (NSB, 2016) indicate that the STEM workforce is aging, with workers aged between 51 and 75 years increasing from 20% of the STEM workforce in 1993 to 34% in 2013. These data show that with increasing job growth and an aging STEM workforce, large increases in available jobs are unavoidable. For example, computer-based occupations can expect over 1 million job openings between 2014 and 2024 (Fayer et al., 2017). Intentional diversification of the STEM education-to-workforce pipeline is a promising method for increasing STEM participation and racial/ethnic parity in STEM careers.

Together, Blacks, Hispanics, and American Indians/Alaska Natives earned 28% of science and engineering degrees awarded to US citizens and permanent residents in 2012 at the associate's level, 20% at the bachelor's level, 18% at the master's level, and 12% at the doctoral level (NSF, 2016). Black students are underrepresented across STEM fields of study, with 6% degree attainment in the physical sciences, 4% degree attainment in engineering, and 5% degree attainment in mathematics (Gasman et al., 2017). These data underscore the absence of diversity in the STEM education-to-employment pipeline. Hispanics comprised more than 5% of workers in S&E occupations in 2010, whereas Blacks comprised 5%, American Indians/Alaska Natives comprised 0.2%, and Native Hawaiians/other Pacific Islanders comprised 0.2% (NSF, 2016). Although Blacks comprise 5% of S&E workers, they represent 12% of the working-age population. Asians represent 19% of S&E workers, but they only represent 5% of the working-age population (NSF, 2016). This racial disparity in STEM employment versus STEM career opportunity indicates expansive space for Black and other URM workers to fill available gaps, which could improve STEM workforce parity.

The United States Innovation and Competition Act of 2021 established a Directorate for Technology, Innovation, and Partnership at the National Science Foundation to "accelerate the development of new technologies and products that improve Americans' way of life, grow the economy and create new jobs, and strengthen and sustain US competitiveness for decades to come (National Science Foundation, 2022)." Positioning students from underserved backgrounds to pursue educational opportunities that will prepare them for future career success is critical for breaking down educational and economic empowerment barriers and helping ensure American STEM competitiveness. Exposing URM students to STEM careers, which are lucrative and abundant, is one resourceful way to introduce them to career options that they may not have considered previously.

The extant literature has identified numerous explanations for the continuing underrepresentation of URM people in STEM education and the workforce, ranging from poor academic preparation and low degree completion rates (National Science Foundation, 2016) to racial isolation and lack of institutional support (Rockinson-Szapkiw et al., 2021; Brown et al., 2016). These explanations emphasize a need to increase STEM participation to reposition America in the global STEM market. Some argue that traditional assessments of STEM performance measure few cognitive abilities and do not examine students' other artistic, technological, critical thinking, or social skills, which are essential 21st-Century Skills. As a result, educators often label URM students as lower achievers, which may limit their future potential (Al-Balushi and Al-Aamri, 2014; Sumarni and Kadarwati, 2020). At the undergraduate level, introductory STEM courses may discourage STEM retention due to high competition and unengaging pedagogy (Gasiewski et al., 2012; Seymour and Hewitt, 1997). However, hands-on, laboratory-based curricula have positively impacted STEM persistence, such that "lab-based education provides students with structured opportunities to develop a STEM identity and gain crucial research skills along the way" (Gasman et al., 2017, p. 15). In addition, academically engaged students are more likely to persist (Nelson Laird et al., 2008). For Black males with STEM interests, who are among the least represented in STEM careers (NSF, 2016), there should be a particular emphasis on nurturing formal and informal interactions to help integrate them into the culture of STEM to help them see STEM as a viable career option (Strayhorn, 2015).

Inclusive STEM

Designing an inclusive STEM curriculum to excite URM students about STEM and expose them to impactful careers could help reshape their identities and increase the number of STEM graduates who are interested in and prepared for STEM careers or graduate

study. Working with researchers from exercise physiology, psychology, biology, and chemistry, one of my collaborative teams set out to infuse laboratory-bench skills and summer research internships into the exercise physiology curriculum at a minority-serving institution (Brown et al., 2018). We used a novel series of chemistry, biology, and biophysics laboratory-bench modules to introduce students to cellular and molecular innovations in STEM that paralleled the evolution of bioengineering in exercise physiology curriculum. Regenerative medicine attracts those with STEM interests, and the field has received considerable attention due to the far-reaching implications of growing tissues and organs in a laboratory setting. We leveraged the excitement surrounding the field of regenerative medicine to engage students. We provided a subset of them with intensive summer research experiences with diverse partners around America like the Wake Forest Institute for Regenerative Medicine and research centers at Miami University (Ohio) and North Carolina State University.

Underrepresented students with STEM career interests face a fundamental disconnect between their academic identity and inclusion in science, such that group membership in STEM has traditionally been framed as White and male, which studies (Hurtado et al., 2008; Chang et al., 2008; Johnson and Elliott, 2020) indicate erodes the potential for URM students to integrate into the culture of STEM fully. Improving URM students' science attitudes could help to bridge that gap. Increasing engagement in a science classroom supports positive science attitude development, which, according to previous studies (Else-Quest et al., 2013) may have positive effects on STEM achievement and persistence. Our proposed psychosocial model (see Fig. 1) linked laboratory-bench techniques to cognitive and behavioral domains. These cognitive and behavioral domains represent pivots for change, such that improving students' attitudes toward science, increasing their confidence to complete science-related tasks, and engaging them in laboratory-based research serve to increase intentions to engage in undergraduate research and to persist in STEM. We positioned URM learners for STEM success by considering the multitude of cognitive and behavioral domains and how our curricular adjustments could support growth in those domains.

Attitudes are highly malleable and contextualized and can be changed due to internal and external factors (Gonzalez et al., 2021). The way URM students see themselves in relation to others, particularly those in STEM fields, changes depending on their narratives about minorities in STEM. Often, STEM learning interventions rely on increased social support to help students overcome perceived deficits. Students who perceive they are receiving adequate social support hold better science attitudes and more positive perceptions of their abilities in math and science (Rice et al., 2013; Rosenthal et al., 2011), and women's STEM identity development is significantly impacted by support factors and early exposure to STEM (Stitt Richardson et al., 2019). Peers or professionals can provide social support within the academic context as role models and mentors that help enhance learners' sense of security and belongingness in STEM (Taylor and Lobel, 1989), and can be particularly impactful when those mentors share lived experiences with URM students. Reducing the barriers to engaging with faculty members for women and URM students can help increase social support that transforms outcomes for URM students (Hurtado et al., 2011). However, attitudes and identity are only two factors in the STEM cultural backdrop that contribute to persistence for URM students. Innovative approaches to exciting students about STEM learning must also be rich in technology.

The future: strengthening the STEM learning ecosystem

My interest in examining issues at the intersection of STEM education, social, behavioral, and economic sciences emerged organically through lived experience and academically through promoting STEM careers to broaden participation among underserved populations. Theoretically, increasing America's STEM workforce requires intentional tending to students' STEM learning ecologies, early support for STEM interest, and technology-rich experiences that excite and engage learners. This may be particularly important for young learners at schools federally designated as "at risk." To meet the needs of diverse 21st century learners, my team and I developed stakeholder-vetted, culturally responsive STEM learning modules that align with Geneva Gay (Gay, 2002) and Gloria Ladson-Billings' (Ladson-Billings, 1995) Culturally Responsive Teaching and Culturally Relevant Pedagogy frameworks.

Fig. 1 Psychosocial framework for promoting stem persistence.

Embedding high-impact, technology-rich experiences into students learning ecology in culturally responsive ways might hasten learners' identity shift, supporting their excitement for STEM and their persistence toward STEM careers.

Our overarching goal for developing these STEM learning modules was to provide opportunities to embed third–fifth-grade students in intensive, technology-rich experiences that fostered STEM interest and engagement and to expose students to a range of STEM careers and promote positive STEM identities with our culturally relevant STEM career-based modules. In addition, we strove to increase students' awareness of STEM occupations, support student engagement via culturally relevant learning activities that enhance learners' identity, motivation, and mindset while also providing students opportunities to learn and practice those interpersonal and intra-personal skills necessary for the STEM workplace. Ultimately, we sought to advance our understanding of fostering student interest and capacities to participate in the STEM workforce.

Toward achieving our stated goals, we developed focus group protocols to extract valuable feedback from Winston-Salem/Forsyth County School teachers, third-fifth grade students, their parents, our STEM career partners, and Winston-Salem State University's STEM Engagement Faculty. Teachers noted that their efforts to expand STEM learning felt stifled by the lack of parental involvement, lack of funding, administrative red tape, and the coronavirus pandemic. Administrators reflected on the difficulty that the global COVID-19 pandemic presented, applauding us for delivering flexible, timely, and exciting modules but lamenting how they could not force teachers, students, or parents to engage during the pandemic. Student feedback showed a clear preference for hands-on STEM learning.

As one component of integrating new technologies to better position students for STEM success, we digitized the Draw-a-Scientist test (Chambers, 1983), a projective test used to assess students' stereotypic perceptions of scientists. Students' Draw-a-Scientist Test (DAST) drawings indicated an increase in female representation, as more of their "scientists" were women, which aligns well with recent DAST literature (Miller et al., 2018). However, that result was complicated because all current science teachers at partner schools were women; thus, students' impressions of what a scientist looks like may have been influenced by their experiences with available science teachers. However, students also drew more diverse characters in diverse environments (e.g., not limiting their scientists' work to indoor environments but also drawing scientists working outdoors). In addition, parents indicated that they needed more education about STEM career options. Still, they wanted their students to have a broad range of career options and be happy with whatever career they chose. These preliminary qualitative findings speak to a dire need for STEM scholars to better understand students' STEM learning ecosystems, which beckons opportunities to collaborate, pool resources, and examine issues at the intersection of STEM education and economics more thoroughly.

My formal training is in community psychology. Because my interests center on promoting best practices for encouraging STEM persistence toward STEM careers, I find the interconnectedness of students' leaning ecologies to be of particular importance. Traditionally, psychology has focused on the individual level of analysis to understand student learning better; however, STEM researchers and interventionists must consider the entirety of students' STEM learning ecosystem, including the learner, their parents, teachers, schools, communities and policies. Reinforcing students learning ecologies gives us inroads to preserve their STEM interests and identities, expose them to STEM career options, and support learning. Uri Bronfenbrenner's Ecological Systems Theory (Bronfenbrenner, 1979) provided the framework for our endeavor. Ultimately, our goal was to create an interconnected, synergistic STEM Learning Ecosystem to facilitate STEM career engagement and strengthen students' STEM identities for third–fifth-grade students, their parents, and underserved schools. In alignment with Bronfenbrenner's bioecological model, we aimed to impact students' microsystems by linking them, their families, and their teachers/schools with culturally relevant and responsive modules for exploring STEM career options. At the mesosystem level, we aimed to connect parents and schools better, increase parental involvement, and build a bridge between STEM learning at school and home. At the macrosystem level, our project targeted schools situated in economically depressed regions catering to underserved students. We deeply considered students' and parents' economic and social pressures to design a STEM curriculum that positively altered their future educational and career trajectories. By building authentic relationships with underserved schools, parents of students studying at underserved schools, teachers and administrators, and community partners, we sought to transform long-held dominant cultural narratives about science and build a pipeline to funnel underserved PreK-12 students toward STEM degrees and careers.

This interdisciplinary project has far-reaching impacts on multiple disciplines and impacts PreK-12 education, postsecondary education, and expands technology use/innovation across the academic, community, and professional settings. This exploratory project aimed to develop culturally relevant, responsive, technology-rich STEM Learning Modules that could be deployed in various settings to positively impact students' learning ecosystems. Our focus on improving learning strategies for students, parents, and teachers impacts STEM education and changes the narrative on STEM career access for underserved students and positions them for lucrative STEM careers. We sought to challenge long-held STEM narratives that exclude persons of color and make it difficult for them to see themselves as scientists, impacting their identity as scientists. Revamping and centering STEM learning in the context of culturally responsive pedagogy should improve key outcomes for underserved students, expand their awareness of STEM careers, and advance social justice in education. To be clear, both psychology and education are impacted by this project positively. Psychology is enriched because refocusing on student's culture and relatable interests and showing them role models from their ethnicity and culture will increase their motivation and perseverance. Education is enriched because using culturally relevant modules to teach will improve teacher-student relationships, regardless of either party's ethnicity/culture, and improve student performance because the material will be more engaging to them.

Conclusions and recommendations

Contemporary trends in STEM education offer new insights into best practices for exciting students about STEM. Exposing them to STEM careers early in the pipeline is a practical and effective way to ensure that they have the time, tools, and resources to attain STEM careers in the future. Of the more important lessons learned from my research is that retaining students in undergraduate STEM courses is much different than retaining students in the STEM education-to-career pipeline. Undergraduate students who choose STEM education have already been supported through the more dangerous early years where their STEM participation could be compromised, so my recommendations for positioning students for STEM careers center on tending to students' early learning ecologies, paving inroads toward reconciling longstanding science stereotypes, and offering experiences that can shift URM students' identities and prepare them for transformative career opportunities. Early support for STEM learning patches holes in the leaky STEM education-to-career pipeline, thus positioning more students for exciting, impactful, transformative STEM careers of the future. To this end, the following recommendations are provided as pillars for research and implementation to help better position students for STEM careers:

1. Work collaboratively across disciplines to elucidate and remediate factors that influence STEM learning and efficacy. Collaborative, interdisciplinary teams are powerful. No individual has all the answers to the pressing questions we have covered in this article but working collaboratively toward a goal of increasing STEM persistence and performance to position students for STEM success is a viable tool for delivering transformative research and designing impactful interventions. Working in silos is counterproductive for positioning diverse students for success.
2. Ensure your work is stakeholder informed and vetted. Despite my strong focus on delivering transformative STEM opportunities for students, I am not a parent and have limited knowledge about what parents want for their children in STEM education. Therefore, I advocate for working closely with not only students as key stakeholders, but also parents, teachers, and administrators. Everyone who interacts with the student has vital information to share about the students' needs, how those needs can best be met, and what resources have already been made available. This is important, because doubling up on resources may or may not be beneficial to students. For example, in our work in third–fifth-grade classrooms, we found that although our target schools were labeled as “at-risk”, previous federal dollars had equipped classrooms with good technology. Each student had digital tablets, smart boards and televisions were in every classroom, and microscopes, beakers, and other tools for science were abundant. It would have been futile to provide more of these tools for science, so working with key stakeholders informed my team about what needs had already been met so that we could meet unmet needs.
3. Although equal numbers of learners have STEM interest during early education (Wang and Degol, 2017), that interest declines precipitously for students with lower levels of STEM self-efficacy (Blotnicky et al., 2018). To support students learning efficacy and position them for STEM careers, we must intervene early and stay the course. We know that science stereotypes strongly impact students' perceptions of scientists, and that concrete perceptions of scientists are apparent as early as the second grade (Chambers, 1983). Early intervention is key, but we must continue supporting STEM engagement across the education-to-career pipeline. Positioning diverse students for STEM careers requires constant nurturing along the developmental pathway to STEM careers.
4. Provide teachers with comprehensive training. Ensuring teachers are trained on contemporary practices for engaging and impactful science for early learners is key to positioning those learners for the STEM jobs of the future. Further, teachers need training in inclusive STEM to support underserved learners' STEM identities. Finally, because technologies evolve rapidly, teachers must also stay abreast of new technologies for STEM learning, be proficient at using those technologies, and comfortable integrating those technologies into sometimes congested daily lesson plans.
5. Communities harbor human capital and empowering those communities to advocate for necessary resources to support human capital is beneficial to individuals, communities, and society. In terms of advocating for STEM, communities may benefit from clear messaging that conveys the transformative power of STEM, how science impacts communities, and how federal and local governments are doling out resources. In speaking with parents, we have found that they were rarely informed about the bevy of resources available to them for their young learners.

Pervasive stereotypes about STEM and a lack of access to necessary resources erodes underserved students' love of STEM learning and persistence toward STEM careers. The imperative driving global STEM competitiveness is ripe with opportunities for those from underserved backgrounds to produce innovations that benefit our global society, so ensuring that the ecological systems in which they learn are geared toward successfully positioning them for the STEM careers of the future is key. Forging a future that is more technologically advanced, inclusive, and just will require a diverse input. Working collaboratively with stakeholders, researchers and implementation scientists can positively impact global STEM outcomes by providing and assessing best-in-class practices for increasing representation in STEM and preparing diverse learners for 21-century careers.

Introduction

Science, technology, engineering, and mathematics (STEM) have been recognized as essential for the technological development and economic growth of a nation (Marginson et al., 2013). Compared to other occupations, careers in STEM domains are rapidly growing in numbers and well-paid. The need of talents in STEM disciplines cause the promotion STEM education in many countries, including the US (National Science Board, 2007), South Korea (Korean Ministry of Education, Science and Technology, 2011), Australia (Education Council, 2015), Singapore (STEM Inc, 2019), and China (National Institute of Educational Science, P. R. China, 2017). STEM education was firstly promoted in higher education in the US, emphasizing the importance of workforce readiness in STEM disciplines, and later at the K-12 stage as well. Presently, STEM education in K-12 not only includes education in each discipline but also integrated STEM education. In other words, STEM is not only taught as discrete subjects but also applied as problem-based learning or project-based learning in real-world context, where usually science, technology, engineering, and mathematics were flexibly applied to resolve problems or questions.

The role of motivation in STEM education

Motivation is a driving force for students' enrollment and participation in STEM learning and career development. Zimmerman and Schunk (2008) summarized that motivation could affect the what, when, and how in students' learning. In STEM disciplines, motivation could positively predict students' learning persistence and future STEM career choices (Bahar and Adiguzel, 2016; Dabney et al., 2012; Maltese et al., 2014; Maltese and Tai, 2011; Robnett and Leaper, 2013; Wang, 2013).

Furthermore, motivation is also a crucial educational outcome in STEM education. Many government initiatives regarding STEM education have put an emphasis on promoting students' STEM motivation (Korea Foundation for the Advancement of Science and Creativity, 2016; National Institute of Educational Sciences, 2017; National Research Council, 2014). Specifically, nurturing students' interest in STEM learning, willingness of entering STEM careers, and STEM identity are highlighted (National Research Council, 2014). For example, in *STEM integration in K-12 education: Status, prospects, and an agenda for research*, these outcomes include STEM course-taking, educational persistence, and graduation rates, STEM-related employment, STEM interest, and development of STEM identity.

Theoretical foundation of motivation in STEM

The definitions of motivation vary and there has been much disagreement about it in literature. According to the definition by Schunk et al. (2014), motivation should be viewed as "the process whereby goal-directed activities are instigated and sustained" and modern motivation theories recognize that such a process involves cognition, affect, and behaviors. This definition emphasizes that the nature of motivation as a process that can only be inferred from individuals' actions (e.g., effort, persistence, choice of tasks) or self-reports.

*Corresponding author

Motivation for STEM learning and motivation for STEM careers are both important topics in the literature for STEM education, both of which are important educational outcomes. To examine motivation for STEM learning, several theories are very informative, including self-determination theory (Ryan and Deci, 2000), self-regulated learning framework (Pintrich, 1999), attribution theory (Kelley, 1967; Weiner, 1972), intrinsic and extrinsic motivation (Ryan and Deci, 2000), etc. In addition, as STEM education has an emphasis on developing students' career interest, motivation theories related to career development, including theories of reasoned action and planned behavior (Ajzen, 1985), social-cognitive career theory (Lent et al., 1994) and expectancy-value theory (Wigfield and Eccles, 2000) are also frequently applied in research in STEM education. These theories provide different lenses to understand the external and internal factors that pull or push individuals to do an action (Hernandez et al., 2013).

Due to the limited length of this article, only two frequently used theories, namely social-cognitive career theory (Lent et al., 1994) and expectancy-value theory (Wigfield and Eccles, 2000) are introduced. These two theories, both derived from social cognitive theory developed by Bandura (1986) are not only applied to explain students' development of STEM learning goals but also STEM career goals and choices.

In social cognitive career theory (SCCT), the career-related outcomes (e.g., interest in science learning, career goal as an engineer, etc.) are determined by the "transactions occurring between persons and their environments" (Lent et al., 2002). SCCT proposed several related models explaining what factors promote individuals' interest and goals (Lent et al., 2002). In these models, the core factors incorporate self-efficacy (i.e., beliefs about an individual's own "capabilities to produce effects") and outcome expectations (i.e., expected results of a particular action), both of which are important contributors to interest and goals in one's learning and in careers, which may influence one's activity selection and practice. And one's activities could promote his/her goal attainment, which may result in providing more sources for self-efficacy and outcome expectations. In addition, background factors, such as gender and family, shed influence on students' learning experiences and shape their choices and outcomes. According to the review by van Tuijl and van der Molen (2016) and the meta-analysis by Lent et al. (2018), the proposed interest and choice model in SCCT has received much empirical support in STEM domains, most of which are quantitative studies focusing on college students.

Similar to SCCT, expectancy-value theory (EVT), which is built upon Atkinson's (1957) and Bandura's (1986) work, emphasized the contributing role of expectancies for success (i.e., the perceived level of success in an activity) and subjective task value (i.e., the perceived value of a task or activity) to students' learning and career goals. In this regard, EVT has a similar foundation with SCCT and some researchers (Parr and Bonitz, 2015) used both approaches in a complementary manner to frame their research. Compared to SCCT, EVT explains the students' forming of motivation-related perceptions and interpretations of experiences in a more detailed and comprehensive manner. For example, EVT provides explanations of how gender role stereotypes and cultural stereotypes of subjects and occupations may have impact on students' choices indirectly through several constructs. In addition, as Eccles and Harold (1991) initially developed the EVT model to explain gender differences in elementary students' and adolescents' mathematics expectancies and the values that affect their choices regarding courses and majors, EVT is very suitable to apply to educational research, including those at the K-12 stage.

From the different theoretical lenses, it is evident to summarize that experiences are the main sources for STEM motivation and that students' interest in STEM subjects/domains are predictive of their STEM career choices. These associations have been supported by many empirical studies in STEM education (Dabney et al., 2012; Lent et al., 2018; Maltese and Tai, 2011). The theoretical lenses are not only informative for researchers to examine, analyze, and explore the formation and maintenance of STEM motivation but also can serve as scaffolds for designing interventions (e.g., Harackiewicz et al., 2012).

Toward a conceptualization of motivation in STEM

Motivation in STEM is thus conceptualized in this article as follows: motivation in STEM is the process in which the STEM learning and pursuit of STEM careers are instigated and sustained. Here, STEM learning involves learning in science, technology, engineering, and technology domains. And STEM careers include careers that use a lot of science, technology, engineering, and mathematics in their work, including scientists, engineers, technologists, etc.

Motivation is a very broad concept with a long history of research and many paradigms (Hernandez et al., 2013). And thus, motivation here is not viewed as a single construct but a spectrum of constructs, which could be named as motivational constructs or motivational variables/factors. These constructs include (but are not limited to) self-efficacy, expectancies, values, goal orientations, and interest.

Factors related to student motivation in STEM

There have been numerous studies on how various external factors, including demographic factors such as gender, age, family background, such as socioeconomic status and parental occupations, school contexts, culture, and learning experiences may impact students' STEM motivation.

A well-known notion named "science capital" promoted by Archer et al. (2014) is a theoretical framework to examine how personal and background factors are related to science aspirations. It is a conceptual framework with a series of variables (i.e., everyday science engagement, future science aspirations, informal science activities, parental attitudes and practices, science teachers and lessons, self-efficacy in science, utility of science qualifications, valuing museums/museum experiences,

valuing science and scientists) to explain the “patterned natures of aspirations and educational participation” of students from age 11 to 16. A further study by [Moote et al. \(2020\)](#) suggested that science capital is strongly related to engineering aspirations but not strongly related to mathematics and technology aspirations. This suggests that science capital may need adaptations to better understand STEM motivation, but it does provide a good example of structuring a family of personal and background factors to understand STEM motivation.

Gender, age, family, culture, and student motivation in STEM

STEM is a field in which important gender differences appear. In general, boys seem to be more motivated for STEM ([Desy et al., 2011](#)). A quantitative study involving 6492 students from grade 3 to 12 indicated that being male is a significant predictor of STEM career aspirations in general ([Holmes et al., 2018](#)). However, differences exist between the STEM disciplines. Health and biology related fields are preferred by girls while physics and engineering related fields are preferred by boys ([Buccheri et al., 2011](#); [Koul et al., 2012](#)). Chemistry seems to be situated in-between these fields but nevertheless preferred by boys ([Cheung, 2009](#)) although the gender effect is not always significant ([Cheung, 2018](#)). The gender gaps and their difference across subject/career domains may be related to the gender-related occupational stereotypes of different STEM subject/careers held by students. And students’ stereotypical views may be influenced by their parents and teachers. As argued in the review by [Van Tuijl and van der Molen \(2016\)](#), teachers’ and parents’ stereotypical values regarding STEM subjects and careers need to be tackled.

Age seems to have an effect on STEM motivation as well. First, gender differences seem to be larger among elder students than among younger school children ([Baram-Tsabari and Yarden, 2011](#)). Further, motivation for STEM subjects declines as students grow older ([Beghetto et al., 2011](#); [Güngören, 2009](#); [Sorge, 2007](#); [Jacobs et al., 2002](#); [Lofgran et al., 2015](#)). This could be an effect of the fact that students dislike school science as [Potvin and Hasni \(2014\)](#) argue. However, it could also be an effect of identity formation among young people. It has been shown that on average, academic self-concepts decline over time because the young people’s individual personalities become more differentiated and more pronounced ([Marsh, 1989](#)). This is a phenomenon observed in general educational psychology which applies also to the field of STEM. Students develop identities (very pronounced motivations) in certain fields while in the remaining areas, motivation falls. This could explain the finding that motivation declines when looking at a group of students. Despite the general tendency of declining motivation in STEM, there are still some studies indicating contrary or mixed results ([Karaarslan and Sungur, 2011](#); [Luo et al., 2019](#); [Fortus and Vedder-Weiss, 2014](#)), which involve different sample choices, age span, and motivational constructs.

One popular metaphor related to the change of STEM aspirations/career choices with age is that of the “leaky STEM pipeline” (e.g., [Ginorio et al., 2002](#); [van den Hurk et al., 2019](#)): many students are interested in STEM but as students grow older, more and more decide not to continue pursuing a STEM career ([Sheldrake, 2020](#)). The metaphor is often used comparing the number of STEM freshmen with university graduates in STEM. A critique of this metaphor of the “leaky pipeline” (see e.g., [Mendick et al., 2017](#)) is that programs designed to fill the cracks in the STEM pipeline focus on supplying the industry with workforce and not on serving the people. However, many scholars adopt this metaphor with the goal to empower groups that are currently underrepresented, in order to support their inclusion in a job market which presents opportunities that could be interesting to them. Still, it seems important to look at the ultimate goals of studies in this area, even if these are not explicitly named.

The influential factor of the family context has long been recognized in motivation theories and career development theories ([Brown, 2002](#); [Ing, 2014](#)). Parents with STEM occupations ([Craig et al., 2018](#)) are predictive of students’ STEM career choices, such as choosing STEM majors in college. Researchers found that parental motivational practices can promote students’ persistence in STEM careers in adulthood through a longitudinal study using a nationally representative sample ([Ing, 2014](#)). An experimental study done by [Harackiewicz et al. \(2012\)](#) indicates that interventions informing parents about the importance of science and mathematics courses (via brochures and websites) may enable the high school students to choose more science and mathematics courses. To summarize, researchers have found that family factors have influence on students’ STEM career interest and such effect can be used to increase students’ STEM motivation.

Culture could play an important role in STEM motivation although knowledge in this area is still limited. The studies on motivation in STEM are not equally distributed around the globe. Research in this field is mainly from the US, Europe, Australia, and Israel and often based on data from these countries ([Potvin and Hasni, 2014](#)). This implies that knowledge on students’ motivation in STEM from other areas is limited. This opens the field for interesting investigations which could help to better understand, for instance, the prevailing gender differences in STEM. There is evidence that the gender relations differ depending on the cultural backgrounds of the students ([Rüschpöhler and Markic, 2019, 2020](#)). This suggests that the associations between the STEM fields and gender are products of the local culture. Learning from other cultures in which these associations are different could be insightful. For example, it seems like in emerging countries, STEM motivation is more pronounced than in developed countries and gender differences are smaller ([Shin et al., 2018](#)). Understanding these phenomena could provide interesting insights.

Another area in which new developments are made is that of identity research in STEM education. One of the reasons for the interest in science identities is the doing-being divide which has been observed: students enjoy doing science but they do not aspire to a career in the field ([Archer et al., 2010](#); [Zimmerman, 2012](#)). Identity formations which are important for choosing and persisting in a STEM career path thus seem to demand a far deeper personal connection with STEM than only interest or positive attitudes. For instance, it has been shown that science identity formation is easiest for middle-class boys belonging to the dominant ethnic group ([Archer et al., 2014](#); [Carlone et al., 2015](#)). Thus, this depends on gender, social class, and race. Identity research in STEM could provide explanations for the underrepresentation of certain groups, namely females ([OECD, 2009](#)) and non-dominant ethnic groups ([OECD, 2008](#)) in STEM fields. Identity research constitutes an interesting approach to STEM motivation research.

Further, it has been argued that it could be more insightful to concentrate on smaller entities when investigating student motivation. In a literature review, [Potvin and Hasni \(2014\)](#) found that gender differences appear more acutely when looking at particular themes in the science subjects and not at a general science or STEM motivation. They refer to a study showing that some students who have very little interest in the general field of STEM do have very pronounced interest in specific, narrow areas ([Yang, 2010](#)).

Formal and informal STEM learning that promotes student motivation in STEM

Literature on increasing STEM motivation through education for STEM is abundant. The reasons for this interest are no doubt manifold but certain rationales seem to underlie many parts of the research in this field. Both formal and informal STEM activities are crucial for initiating interest in STEM domains ([Young et al., 2017](#)) and the trigger for students' STEM motivation can start early in childhood ([Van Tuijl and van der Molen, 2016](#)) and happen across a wide age spectrum ([Maltese et al., 2014](#)). This argument has been supported by several studies exploring how students develop their motivation in STEM using a retrospective approach ([Dabney et al., 2012](#); [Maltese et al., 2014](#); [Maltese and Tai, 2010](#)). For example, [Maltese et al. \(2014\)](#) compared the reported experiences of STEM majors and non-STEM majors and summarized that the pathways to STEM are very diverse without a clear preferential way. [Maltese and Tai \(2010\)](#) analyzed experiences reported by scientists and graduate students and found that both school-related activities and self-initiated activities accounted for their interest in science. And it is worth noting that 65% of the participants reported an initial interest in science before middle school.

Among students' educational experiences, some free-choice STEM activities, such as assembling machines ([Maltese et al., 2014](#)), participation in STEM clubs and competitions ([Sahin, 2013](#)), talking to others about science and reading/watching science materials ([Dou et al., 2019](#)) are predictive of students' future STEM career choices. On the other hand, researchers found that participation in advanced placement (AP) courses and students' achievement are not predictive of students' choices of STEM major ([Maltese and Tai, 2011](#)). It seems that the experience of STEM learning which is motivated by students' inner interest rather than extrinsic motivation is more closely related to students' future STEM career choices.

One important consideration in the literature regarding interventions and STEM motivation are methodological difficulties. Articles about interventions which did not increase student motivation are scarce ([Potvin and Hasni, 2014](#)) although negative results would be very insightful for differentiating between interventions that work and those that do not. Many extracurricular programs like STEM camps (e.g., [Halonen and Aksela, 2018](#)), trips to the industry or to university (e.g., [Glowinski and Bayrhuber, 2011](#)), museum visits (e.g., [Martin et al., 2016](#)), competitions ([Höffler et al., 2017](#)) etc. seem to be beneficial for motivation in STEM. They allow for science learning in non-formal settings which could promote a transition of science—framed as being a school subject—toward science, framed as being a field of leisure interest. However, one problem with these studies is that they usually concern selected students who have opted to participate in the activity in their spare time. It is not possible to derive conclusions about how to increase STEM motivation among those who do not opt for this kind of programs. Furthermore, showing that an intervention did increase motivation does not yet allow to infer how this influence might be wielded. Making sure to avoid prior selections ([Potvin and Hasni, 2014](#)) could be one factor for improving research in this field. Mixed methods design studies with quantitative assessments of the strength of motivation in STEM and qualitative analyses of how motivation is increased could be interesting as well.

Among the multitude of factors that might make interventions successful in increasing motivation in STEM, several factors seem to be commonly recognized in current research literature. First, making STEM education relevant seems to be an important factor. Relevance is a term that often remains undefined and unconceptualized. It is sometimes translated with “contextualization” in STEM education although the terms differ from one another. Relevance, according to the model by [Stuckey et al. \(2013\)](#), is a three-dimensional construct comprising the dimensions of relevance for the student as an individual, for the student as a member of society, and for the student as a person who needs to qualify for a future job. Contextualization is a technique that can increase relevance on different dimensions. Potvin and Hasni conclude in their review that interventions containing contextualization “reported positive effects but from very different approaches” (2014, p. 105). This could be a reflection of a lack of differentiation between the aspects of “contextualization”. However, contextualized STEM learning seems to be beneficial for motivation (for an overview see [King, 2012](#)). The perceived connections to real life could predict students' career choice about whether to enter a science major at the college level ([Hutchinson-Anderson et al., 2015](#)).

Some STEM interventions increase relevance by incorporating information and participation of STEM professionals in the curriculum/activities. Some researchers provide students with videos about STEM professionals' work ([Colston et al., 2017](#); [Wyss et al., 2012](#)) and some researchers invite STEM professionals to give seminars ([Cantrell and Ewing-Taylor, 2009](#)). In addition, some researchers invite STEM professionals to work with students ([Barab and Hay, 2001](#)). These approaches may enable students to understand how STEM knowledge and skills serve the society and encourage them to pursue STEM careers in the future. The results showed that, students' exposure to interviews about STEM professionals contributes to an increase in career interest ([Colston et al., 2017](#)).

Second, besides increasing the relevance for the students, researchers have argued that the level of integration of STEM domains seems to be beneficial for motivation in STEM fields ([Thibaut et al., 2018](#)). Solving real-world STEM problems in STEM class usually requires students to apply knowledge and skills from several disciplines in a flexible way, making STEM education naturally related to the integration of knowledge and skills in science, technology, engineering and mathematics. [Yoon et al. \(2014\)](#) found that interventions working with science, technology, and engineering as an integrated subject could promote elementary students' engineering career identities compared to interventions without integration. A meta-summary of qualitative findings regarding

STEM education showed that it could promote students' willingness of choosing STEM professions (Kanadli, 2019). In addition, there are also some meta-analysis studies supporting the argument that STEM integration is beneficial for students' mathematics achievement (Mustafa et al., 2016), or more effective in promoting achievement in general, compared to other forms of integration (e.g., E-M and M-S-T) in integrated STEM education (Becker and Park, 2011). And these effects of STEM integration on students' achievement may further help build STEM motivation.

Third, inquiry-based learning may promote STEM motivation. Inquiry-based learning is one of the major approaches in STEM education (Thibaut et al., 2018) and has a long tradition in science and mathematics education, which is based on students engaging in a research process. There are different levels of inquiry-based learning which allow for more or less degrees of freedom and structuration by the teacher (see Rönnebeck et al., 2016 for an overview). Studies have indicated positive effects of inquiry-based learning on student motivation (Cairns and Areepattamannil, 2019; Chin and Osborne, 2008). Besides these three important factors (contextualization, inquiry-based learning, and the level of integration of the STEM subjects into one single domain), many other aspects in learning might be important for promoting STEM motivation. For further literature, see the review by Potvin and Hasni (2014).

Measurement of motivational constructs in STEM

Most existing measures for motivational constructs in STEM focus on the cognitive or affective domain of motivation. There are already many existing instruments for measuring science motivation (e.g., Glynn et al., 2009; Tuan et al., 2005), technology motivation (Liou and Kuo, 2014), engineering motivation (e.g., Mamaril et al., 2016), and mathematics motivation (e.g., Lim and Chapman, 2015), and some motivation-related measures for STEM as four separate-but-related domains (Guzey et al., 2014; Kier, 2014; Luo et al., 2019; Oh et al., 2013; Toker and Ackerman, 2012; Tyler-Wood et al., 2010; Unfried et al., 2015). The following review will put more emphasis on a few measures for STEM as four related domains.

As most of the existing measuring tools target different sub-categories of motivation, or some motivational constructs, the existing measurement tools related to STEM motivation also vary regarding their names, structures, and functions. For example, Oh et al. (2013) developed the Educational and Career Interest in STEM measure for high school students, which contains 12 items measuring students' interest in the four STEM domains respectively and 8 items measuring their interests in STEM as a unified concept. The tool has been validated on high school students with a Cronbach's alpha of 0.88 and three factors, namely educational and career interest in science, technology, and mathematics. The shortcoming of the measure is that the items regarding engineering were deleted finally, which may be caused by students' unfamiliarity with engineering.

In addition, Kier et al. (2014) developed a survey called STEM career interest survey (STEM-CIS) based upon SCCT. The STEM-CIS has items on personal goals, outcome expectations, interests, personal inputs, and contextual supports and barriers. The survey has been validated on 4th to 8th grade students and factor analysis confirmed that it has four subscales for science, technology, engineering, and mathematics respectively with a total Cronbach's alpha of the subscales ranging from 0.77 to 0.89.

Only a few measures can be used to examine the behavior aspect of motivation. Luo et al. (2019) developed an instrument measuring students' continuing motivation in STEM (STEM CM) with reference to the science continuing motivation scale developed by Fortus and Vedder-Weiss (2014). STEM continuing motivation is a specific type of motivation that exhibits students' tendencies of engaging in free-choice STEM-related activities. The STEM CM measure was validated using Rasch analysis on 7th and 8th grade students and has four subscales on science, technology, engineering, and mathematics respectively, with a total Cronbach's alpha of 0.91.

The above-mentioned measures all treat STEM as four separate but related subjects. There are also a few measures for motivational constructs that treat STEM as an integrated field (Luo et al., 2021; Milner et al., 2014; Nugent et al., 2015). These measures usually treat STEM learning as learning through practices that incorporate multiple STEM subjects. For example, the self-efficacy for STEM activities (STEMaSE) survey was developed and validated on upper-elementary students to evaluate their self-efficacy in STEM activities through practices such as "to test and compare different solutions" and "to represent the data with graphs" (Luo et al., 2021). Moreover, the STEM Career Interest Test and STEM Career Self-Efficacy Test developed for college students measure their career interest and self-efficacy in tasks such as "measure the speed of electrons" and "design a diagnostic routine for a power plant" (Milner et al., 2014). All these three surveys have one factor, according to exploratory factor analysis and confirmatory factor analysis, suggesting students' self-efficacy and career interest in these tasks exhibited an integrated nature when measured.

Concluding remarks

To date, we have learned from literature that STEM motivation is a driving force and an important outcome of STEM learning. It may start early in an individual's life and there is not a singular pathway but various ways for its development. There are gender differences in STEM motivation in different STEM disciplines. Generally, students' STEM motivation seems to decline with age. Family background as well as parental influence seem to play a role in students' STEM motivation whereby parent education may help promote students' STEM motivation.

Abundant literature has shown the positive influence of both informal and formal education on STEM motivation. However, not much is yet known about which specific factors in the integrated STEM interventions work on students' motivation. Better contextualizing (including linking STEM learning with information about STEM careers), a higher level of STEM integration, and the use of the inquiry-based approach seem to have positive effects on students' motivation. Future studies are needed to elucidate what interventions do and which do not promote STEM motivation.

Some suggestions for future studies are proposed as follows. First, there are many widely applied theories (e.g., EVT, etc), or perspectives (e.g., pipeline metaphor, science capital) that can be applied in STEM education research as frameworks to analyze the formation, maintenance, and shifts in students' motivation. The usage of such theories and perspectives may situate the research to a well-grounded foundation of previous studies and may serve as reference in designing interventions promoting students' STEM motivation.

Second, many previous studies regarding STEM motivation do not explicitly specify the level of integration or the levels of integration are inconsistent between the intervention and the measurement. The level of integration in STEM education suggested by English (2016) can be used as a reference. According to English (2016), the integration level of STEM ranges from disciplinary to multidisciplinary, interdisciplinary, and transdisciplinary. Disciplinary STEM indicates that knowledge and skills are acquired in each of the four domains in STEM separately. The second level of integration, multidisciplinary, means that knowledge and skills are learned from each domain but under a common theme. The third level is named interdisciplinary, in which knowledge and skills that are related are learned from more than one discipline to deepen the understanding. The highest level of integration is named transdisciplinary, which means that knowledge and skills are learned from more than one discipline and are applied to real-world problems or projects. For future studies, it will be a good practice to identify the level of STEM integration as a theoretical stance and to keep the level of integration consistent between the interventions (if applicable) and the measurement.

So far, many studies regarding STEM motivation treat STEM as disciplinary or multidisciplinary concepts. With the development of STEM education, more studies regarding higher levels of STEM integration (i.e., interdisciplinary or transdisciplinary) will be needed as they are promoted in the education community as a future trend. Nevertheless, pursuing higher levels of STEM integration, on the other hand, increases the difficulty in designing interventions and measuring instruments.

Introduction

Interest and popularity of STEM education that integrates or combines science, technology, engineering, and mathematics has been raised among scholars and educators for teaching and learning in the past few decades. The demand for a STEM-educated workforce has gained increased emphasis from urgent global challenges, including climate change, population, resource management, health and energy issues (Bybee, 2010). All of these complex global issues which can only be addressed by the integration of knowledge and skills of multiple disciplines (Thomas and Watters, 2015; Kelley and Knowles, 2016; Roehrig et al., 2021), require building capacity and international scientific engagement in STEM education (Clark, 2014). In the United States, national policy documents National Academy of Science and National Academy of Engineering, and Institute of Medicine (2007), Next Generation Science Standards (NGSS) (NGSS Lead States, 2013) call for reform to K-12 STEM Education which aim to prepare next generation students for STEM careers and professions (Dori et al., 2018; Roehrig et al., 2021; Shernoff et al., 2017). In particular, since science education included engineering practice and content in the NGSS, how to incorporate integrated multi-disciplinary content into science education has become a key issue (Kim and Oliver, 2018). Meanwhile, some scholars and practitioners have been concerned about over-emphasis on the STEM career pathways and STEM-capable workforce readiness, and application of STEM knowledge with economic perspective of STEM education, and have led the discussions of STEM literacy (Mohr-Schroeder et al., 2020).

To support all diverse students' equity and development of real-world problem-solving competencies and informed decision-making in everyday lives (NGSS Lead States, 2013; ITEEA, 2007; ABET, 2013; NCTM, 2000; NAE and NRC, 2014; NRC, 2012), STEM literacy has also received attention among scholars and educators in STEM education. Mohr-Schroeder et al. (2020) suggested a definition of STEM literacy as “dynamic process and ability to apply, question, collaborate, appreciate, engage, persist, and understand the utility of STEM concepts and skills to provide solutions for STEM-related personal, societal, and global challenges that cannot be solved using a single discipline (p.33)”, highlighting the needs of integration among disciplines to solve problems. There is no one-agreed definition of STEM literacy due to its dynamic and responsive nature in our continuously changing society (Cavalcanti, 2017; Cavalcanti and Mohr-Schroeder, 2019; Zollman, 2012; Mohr-Schroeder et al., 2020). However, one obvious commonality of defining STEM literacy is that STEM literacy should be considered as an integrated literacy (Zollman, 2012). In the broader sense of integrated literacy, we also found many schools are incorporating non-STEM disciplines, exploring the integration of STEM and non-STEM disciplines such as art and humanities and social sciences (e.g., STEAM movement is referring to the case of integration STEM and arts). Some scholars express the view that the STS (Science, Technology and Society) or SSI (Socio-Scientific Issues) movement can be considered as integrated STEM/STEAM education (Tarnoff, 2010). Further, Owens and Sadler (2020) highlighted that SSI can serve as meaningful contexts in STEM curriculum as SSI situates learners to solve real-world problems in an integrated manner (Zeidler, 2014).

Integrated approaches to STEM education have been recognized for their significant advantages in that students can apply multi-disciplinary concepts, critical thinking, collaboration and creativity to real-world problems (Burrows and Slater, 2015; Shernoff et al., 2017). However, research have found that making interrelationships/crosscutting connections among the STEM disciplines are complex and requires deliberate, purposeful and strategic approaches to teach STEM content in implementation, so that students understand how STEM knowledge is conceptually and contextually linked and applied to real-world problems (Kelley and Knowles, 2016; Roehrig et al., 2021). While integrated approaches to STEM education have been emphasized with reform efforts, there are still not many well-developed curriculums, and an integrated way into classroom instructions and assessment

is uncertain and needs a clearer picture of the integrated STEM. Despite the recognized benefits of integrated STEM education, a number of barriers were also identified and discussed in teaching integrated STEM curriculum of many STEM teachers and professionals (e.g., lack of confidence in teaching integrated STEM curricula) (Cunningham and Carlsen, 2014; Cunningham et al., 2005; Honey et al., 2014; Kim and Oliver, 2018; Brophy et al., 2008; Roehrig et al., 2021).

In this article, we begin with a brief review of the ways in which integrated STEM has been conceptualized in the research literature, followed by an overview of research that has focused on the way curriculum and assessment of integrated STEM has developed. Since our conceptions of assessment are not separable from the curriculum and instruction, we will describe assessment in alignment with implementation of curriculum and instruction and present a model that aims to suggest how the four disciplines of STEM can get equal emphasis in classrooms. Concluding this article, we will discuss implications on teacher education and professional development in relation to the assessment of integrated STEM.

Background and defining STEM education

Influences from changes in the broader society have led to changes in educational goals and curriculum reforms (DeBoer, 2014). In the 1983 report, *A Nation at Risk*, the National Commission on Excellence in Education (NCEE) in the US suggested a need for improvement of mathematics and science education with emphasis on higher expectations for students and also spurred educational reforms to integrate or make connections among curriculum (Jackson et al., 2020; DeBoer, 2014). In 1990s, while the discussions on the nature of integration were centered around the integration within science and mathematics, there were some traces of the early ideas of STEM integration of technology, engineering, and mathematics in science (*Science for All Americans*) (Herschman, 1988) and even included social studies into that integration (Anon, 1992; Jackson et al., 2020). In this time of the curriculum development, various curriculum design formats for integration of science and mathematics have been suggested: independent science or mathematics, science focus (math as a subset of science), mathematics focus (science as a subset of mathematics), some overlap between science and math, and a major overlapped program (Czerniak et al., 1999; Jacobs, 1989; Lonning and Defranco, 1997). Davison et al. (1995) suggested five types of integration for developing integrated curriculum: discipline specific (e.g., integration within a discipline), content specific (e.g., integration of mathematical and scientific concepts), process (e.g., integration of scientific processes such as collecting data and mathematics standards such as statistics), methodological (e.g., integration of the learning cycle or models for teaching and learning science and mathematics), and thematic integration (e.g., thematic topics for integration between disciplines).

Later on, until the 2000s, STS education was focused on the inclusion of technology or engineering into science and mathematics, and little attempt was made to create an integrated way of STEM learning in terms of equal attention to two or more disciplines (Bybee, 2010; Sanders, 2009; Wang et al., 2011; Kelley and Knowles, 2016). Bybee (2010) made the point that the term STEM has been used “as a generic label for any event, policy, program, or practice that involves one or several of the STEM disciplines” (p. 30) and the education community needed to clarify the meaning of STEM beyond the general label. Bybee (2010) asserted that STEM should mean increased emphasis on technology and engineering in K-12 education, and an integrated curricular approach to deal with global issues such as energy efficiency or environmental quality.

Sanders (2009) presented the meaning of STEM education focusing on the integration of subjects as approaches of “teaching and learning between/among any two or more of the STEM subject areas, and/or between a STEM subject and one or more other school subjects” (p. 21). In addition to the idea of combining STEM disciplines, Stohlmann et al. (2012) made the point that integrated STEM education is not necessarily involved in all four STEM disciplines and can be utilized as extended across multiple class sessions rather than integration into one class. Moore et al. (2014a,b) also addressed STEM integration as combinations of some or all of the STEM disciplines and emphasized the connections between the subjects in real-world problems. Kelley and Knowles (2016) more organically defined integrated STEM education as “the approach to teaching the STEM content of two or more STEM domains, bound by STEM practices within an authentic context for the purpose of connecting these subjects to enhance student learning” (p. 3).

Conceptualizing “integrated” STEM learning

Beyond the definitions, Kelley and Knowles (2016) also proposed a conceptual framework for integrated STEM education to provide an ideal picture with full potential of the integrated STEM focused on secondary education. This conceptual framework includes four main components as an integrated system: *engineering design, scientific inquiry, technology literacy, and mathematical thinking* by engaging students in a *community of practice in the situated STEM learning*. Moore et al. (2014b) suggested six tenets for designing integrated STEM curriculum which emphasized the engineering design process in the STEM curriculum: A motivating and engaging context, an engineering design challenge, the opportunity to learn from failure through redesign, math and/or science content, student-centered pedagogies, and an emphasis on teamwork and communication.

In the book, *STEM Integration in K-12 Education: Status, Prospects, and an Agenda for Research* (NAE and NRC, 2014) introduced a comprehensive framework for integrated STEM education in K-12 education. The committee identified the learning outcomes of *integrated STEM education including* 21st century competencies, STEM interest, STEM identity, ability to make connections among STEM disciplines for students, as well as STEM-related employment or STEM graduate rates.

Table 1 Types and degrees of STEM integration.

<i>Types and degrees of STEM integration</i>	<i>General description</i>
Monodisciplinary	Content learned in separate/individual disciplinary classrooms
Multidisciplinary	Content learned separately but connected through a common theme or real-world issue Each discipline would be identifiable within the curriculum (Lederman and Niess, 1997) Can take place in a single classroom or through curricular alignment across multiple subject area classes (Drake, 1998; Fogarty, 1991)
Interdisciplinary	Focus on connections between disciplines (Gao et al., 2020), and interdisciplinary content, skills and practices from two or more disciplines connected through a common theme or problem or issue (Roehrig et al., 2021).
Transdisciplinary	Each discipline would be difficult to distinguish from one another (Lederman and Niess, 1997). Beyond the disciplinary constraints (Gao et al., 2020) and not much attention to traces of the individual disciplines (Klein, 2008) Content from two or more disciplines are applied to real-world problems, with the learning focus on the real-world problem or issues (not different subject areas) “Combining ideas and subject matters of different disciplines into a seamless whole” (Lederman and Niess, 1997).

This summary was constructed adapted from Roehrig et al. (2021) and Gao et al. (2020)'s categorizations of the nature of and levels of STEM integration (which initially adapted from Vasquez et al., 2013) as a continuum from disciplinary to transdisciplinary as the integration increases.

Various terms on the integrated STEM education have been used to describe the connections (e.g., multidisciplinary or cross-disciplinary, etc.) within and across STEM disciplines. Although the complexity and ambiguity with diverse views on the integrated STEM, there are four main categorizations have been identified based on the nature of and levels of STEM integration from the literature: (mono-)disciplinary, multidisciplinary, interdisciplinary, and transdisciplinary approaches (Drake, 1998; Lederman and Niess, 1997; Honey et al., 2014; Moore and Smith, 2014; Vasquez et al., 2013; Gao et al., 2020; Roehrig et al., 2021). Table 1 shows a summary of the categorization with the types and degrees of STEM integration.

Due to the diverse views on the nature and development of proficiencies in STEM education, a focus on the nature of integration has been increased and generated needs for further research in STEM education (English, 2016; Marginson et al., 2013).

Engineering design as a key integrator in STEM curricula

Many researchers have shown that, in the development of the integrated STEM curriculum, engineering design serves as an essential vehicle, entry point, catalyst, or integrator for all STEM disciplines in that engineering design provides a platform for equal multidisciplinary connections and applications of core concepts and skills in real-world situations (NAE and NRC, 2014; NRC, 2012; Frykholm and Glasson, 2005; Barnett and Hodson, 2001; Moore et al., 2014a,b; Kelley and Knowles, 2016; Kim et al., 2019b). In this line of research, Moore and colleagues have provided empirical findings that engineering is an essential driver or connector that can integrate STEM disciplines in K-12 education (Glancy et al., 2017; Guzey et al., 2014; Moore and Smith, 2014; Moore et al., 2014a,b; Shernoff et al., 2017). Further, engineering design tasks offer a consistent storyline (Roehrig et al., 2021) bound by STEM practices (e.g., engineering practices) which function as a contextual integrator within curriculum (Kelley and Knowles, 2016; Reynante et al., 2020; Roehrig et al., 2021).

Roehrig et al. (2021) emphasized the *curricular coherence* of STEM units. The authors argued that the coherence of ideas within curriculum is a critical factor for students to develop explanations and conceptual understanding when those are meaningfully linked and richly integrated. In the article, Roehrig et al. (2021) proposed a visualized tool (i.e., CFG, *Conceptual Flow Graphic*) which organized chronologically with main concepts, connections among concepts and lessons, and strength of connections to assess the quality integration of STEM curricula. In an integrated STEM curriculum, it is important to give students the opportunity to understand the connections between STEM disciplines (English, 2016; Honey et al., 2014; Moore et al., 2014a), and the opportunity to explicitly recognize how STEM disciplines are integrated in the contexts (Reynante et al., 2020; Roehrig et al., 2021).

Innovative approaches to STEM curriculum

The development of an integrated STEM curriculum requires complex and cohesive organization of STEM disciplines through tangible forms for implementation such as project-, problem-, or theme-based learning approaches. In turn, the tasks in these innovative curricula lead to assessment of student learning through the tangible products produced (e.g., design product in an engineering design project). Regarding the instructional design for the integrated STEM, problem-based learning and project-based learning were adopted as a form of “engineering design challenges” in most cases (Harwell et al., 2015; Hmelo et al., 2000; Mehalik et al., 2008; Moore et al., 2014a; Sadler et al., 2000).

Problem-based learning and project-based learning have many similarities, and both approaches involve student-centered learning and helping students to develop problem solving and higher order thinking abilities. Problem-based learning promotes; (1) learning organized content, (2) problem-solving abilities, and (3) independent learning skills and self-reflection, as it is a student-centered learning approach in which teachers act as facilitators (Hung et al., 2008). However, there are mixed research results concerning the impact of problem-based learning on students' academic achievement. Several studies have shown that when students engaged in problem-based learning curricula, no significant difference or even underperformance on assessments of content knowledge acquisition were found compared to students who were taught using a traditional teaching method (Gallagher and Stepien, 1996; Mergendoller et al., 2000; Perrenet et al., 2000).

Compared with problem-based learning, project-based learning emphasizes developing teamwork and communication skills through group work. Project-based learning typically takes a longer time, focuses on the application of knowledge (Mills and Treagust, 2003) and concerns the development of cognitive and practical skills than simple acquisition of content (Heywood, 2005). Project-based STEM learning approaches have been considered as student-centered, meaningful, engaging, authentic and collaborative learning experiences, and recognized as a powerful method for; (1) integrating knowledge from multiple disciplines (Bell, 2010; Heywood, 2005; Mills and Treagust, 2003), (2) acquiring a deep understanding of science knowledge by actively constructing knowledge (Krajcik and Blumenfeld, 2006), (3) engaging in self-evaluation of both learning processes and social interactions (Bell, 2010), (4) promoting students' creativity, critical thinking and problem-solving skills through situated inquiry (Stohlmann et al., 2012; Shernoff et al., 2017; Moore et al., 2014a,b; Krajcik and Blumenfeld, 2006) and (5) use of learning technology in the integrated STEM instructions (Krajcik and Blumenfeld, 2006). It is clear that all these learning outcomes that students can develop through project work cannot be assessed through traditional assessment techniques (e.g., written examinations) such as planning or synthesizing abilities.

Assessment of student learning in integrated STEM

Assessment is an essential part of education for both teachers and students in that assessment clarifies learning goals, performance expectations and information on what and how to assess (Biggs, 2003; Douglas et al., 2020). Assessment can also be used to evaluate curriculum or effectiveness of teachers beyond interpretation of individual students' performances. Assessment can be defined as "a formal way to determine students' status with respect to variables of interest" (Popham, 2010, p. 7) as well as a way to determine where students stand in relation to the learning objectives to make instructional decisions to advance student learning (Black and William, 2009; National Research Council, 2001). The latter assessment is called as formative assessment focusing on the students' dynamic learning progress, which can be implemented in a formal and informal manner when teachers gather and analyze assessment data in the classrooms (Bell and Cowie, 2001; Cowie and Bell, 1999; Furtak, 2012; Araceli Ruiz-Primo and Furtak, 2006; Kim et al., 2019a,b). We submit that the assessment of integrated STEM learning can (and should) be also assessed both formally and informally, as well as in summative and formative ways. Pellegrino et al. (2001) highlighted assessment as "a process of reasoning from evidence" of what students know and what students can do, proposing closely linked three main components of assessment: *cognition*, *observation* and *interpretation*. *Cognition* refers to the knowledge, skills and abilities students develop in the target domains. The *observation* refers to the types of assessment tasks to be able to collect evidence of the targeted competence, and the *interpretation* refers to the process of reasoning about students' competence based on the observed data of student performance (Pellegrino et al., 2001; Pellegrino, 2014; Gao et al., 2020; Douglas et al., 2020). These components should be triangulated for proper interpretation of the observed student learning data in relation to the targeted domains in the assessment.

Valid assessment of student learning in STEM is key to determining the success of an innovative curriculum and student performance that are aligned to the spirit of integrated STEM. The *Committee on Integrated STEM Education* made recommendations to guide multiple stakeholders in designing initiatives and developing curriculum and assessments for integrated STEM, as well as further research agenda to support the integrated STEM education (NAE and NRC, 2014). Empirical research support in this area of the integrated STEM learning and assessment needs to be tested and investigated. In particular, it has been a challenge to develop valid and reliable assessment tools in relation to the integrated STEM learning outcomes.

How researchers have conceptualized the integrated STEM, and developed and implemented curriculum are important to better understand the assessment of the integrated STEM learning outcomes in alignment with the learning goals. In the next section, we will review the research that has focused on the assessment of integrated STEM learning and conclude with the discussion of the implication of integrated STEM assessment.

STEM competence

To assess integrated STEM learning, we need to identify what to assess and what we count as evidence of accomplishment of integrated STEM learning outcomes. Bybee (2010) addressed STEM competencies for students to achieve in the 21st century which included identifying STEM issues, explaining issues from STEM perspectives, and using STEM information.

Douglas et al. (2020) presented a conceptual framework of "integrated STEM competence" as "the ability to combine knowledge, skills and abilities (KSAs) from one or more disciplines to solve problems across a wide range of authentic contexts" (p. 234). These authors identified that STEM competence includes *multidimensions* such as *knowledge*, *skills*, *processes* dimensions

to engage in ideas, concepts and practices of STEM to solve authentic problems, reflected from multiple reform documents (NRC, 2000; Krzywacki et al., 2012), however, the multidimensions have not been agreed upon among the reform documents. For example, the *Framework for K-12 Science Education* (NRC, 2012) presented three dimensions of science teaching: *disciplinary core ideas*, *crosscutting concepts* and *science and engineering practices* which serve as learning objectives within science. Although no single approach was acknowledged on how to integrate the three dimensions into standards, curriculum, instruction and assessment, it was clearly stated that “performance expectations must be designed to gather evidence of students’ ability to apply the practices and their understanding of the crosscutting concepts in the contexts of specific applications in multiple disciplinary areas” (NRC, 2012, p. 218). This document introduced the “science and engineering practices” as an integration of multiple disciplinary areas, and also emphasized the importance of the integration of understanding of concepts and practices. Gao et al. (2020) classified the learning outcomes of the integrated STEM programs as four dimensions: *knowledge, skills, practice and affective domain* based on the learning objectives of Bloom’s taxonomy, examining research in assessment of integrated STEM combined with the levels of integration among disciplines.

Gane et al. (2018) also confirmed that these integrated competences are multidimensional and claimed they should be assessed concurrently. This suggests that students can (and will) demonstrate targeted multidimensions in their performance, at the same time, the assessment tasks should be designed to gather evidence of the multidimensions of student competencies related to the integrated STEM learning (Gane et al., 2018; Harris et al., 2019; Douglas et al., 2020).

Although models and frameworks have been proposed for the assessment of integrated STEM and its multidimensions, we acknowledge that concrete examples with practical standards and rubrics with meaningful connections among multiple disciplines are still rare, and need further research in this area. In addition, the STEM competences can be promoted “holistically” from the engagement of STEM practices, exploring the relationship between ideas within and across multiple STEM disciplines (NRC, 2014; Douglas et al., 2020). Although STEM curricula have been increased and implemented in schools, research has reported that very few STEM assessments are conducted in an integrated way, as well as merely aligned with curriculum and instruction, assessing memorized content and practices (Douglas et al., 2017).

Degree of integration and STEM assessment

The benefits of the integrated STEM curriculum in student learning have been emphasized, and the ability to make connections among multiple disciplines is considered as one of the most important learning outcomes in STEM education (NAE and NRC, 2014). However, research in the area of integrated STEM assessment indicated there is little scholarship on the explicit assessment of students’ understanding of connections among multiple disciplines in assessment tasks.

Gao et al. (2020) conducted a comprehensive systematic review of 49 empirical research on assessment of interdisciplinary STEM education focused on secondary and tertiary level for the last two decades. These authors analyzed the empirical studies, creating a matrix with two main dimensions for the analysis: (1) the nature of disciplines (monodisciplinary, interdisciplinary and transdisciplinary) and (2) learning objectives (knowledge, skills, practice and affective domain). The authors found, although explicit and purposeful connections among the STEM disciplines in STEM curricula have been emphasized in the initiatives and standards (Moore et al., 2014a,b; Honey et al., 2014; English, 2016; Reynante et al., 2020; Roehrig et al., 2021), most studies on the assessment of STEM focused on objectives within individual monodisciplines, such that monodisciplinary knowledge was assessed within 38.8% of the total articles, and monodisciplinary affective domains within 32.7% of the total articles. This was true even in cases of the STEM curricula implemented in integrated ways. In terms of dimensions of assessment, it is also reported that knowledge and affective domains were paid attention to dominantly in the assessment of STEM. In particular, the affective domain was the most popular targeted dimension for STEM assessment, including awareness, beliefs, motivation, self-efficacy, interest toward STEM disciplines, and willingness to major in STEM or attitudes toward STEM related careers.

In cases of connections among STEM disciplines, the analysis showed that science and engineering were the dominant disciplines in studies on assessment of integrated STEM (82% of the total articles included both science and engineering). It was reported that interdisciplinary categories (39% of the total articles) were reported least in assessment in relation to the degree of integration. The transdisciplinary category was the second most popular in the degree of integration: transdisciplinary affective domains (36.7% of the total articles) and transdisciplinary skills (22.4% of the total articles). These findings highlight that not only interdisciplinary and transdisciplinary assessment of student understanding, but also skills or practices of integrated STEM disciplines are less targeted which indicates that the assessments are not well aligned with their curriculum designs and key expected outcomes in the integrated STEM education.

Many scholars have discussed the assessment issues that arise from the study of innovative teaching strategies in educational communities (Brophy et al., 2008; Hung et al., 2008; Mills and Treagust, 2003). These researchers argue that anticipated student outcomes from problem-based or project-based learning, such as high-level thinking skills, motivation to learn, teamwork, or communication skills, cannot be assessed properly by using traditional assessment methods. On the other hand, school administrators need clear and unequivocal evidence of student achievement that show the effects of innovative strategies. However, scholars have acknowledged that teachers have difficulty in assessing student outcomes when they are implementing a new instructional method. Ideally assessments need to be aligned with the curriculum which reflect learning objectives. However, scholars and educators have been concerned about the misalignment between the curriculum and assessment in education and claimed the primary

source of performance expectations and learning outcomes should be learning goals and tasks in the curriculum (Yager and Tamir, 1993; McTighe and Wiggins, 2004). In a similar manner, it is essential to clarify assessment domains and evidences of desired competence that show effectiveness and improvement in students' abilities with STEM curricula. However, the concerns on the discrepancy between the goals of developing student competence in integrated STEM and STEM assessment, which have focused on isolated factual knowledge and procedural knowledge of STEM have been raised (Pellegrino, 2014; Douglas et al., 2020).

Approaches to assessment of integrated STEM

The development of appropriate assessment methods and knowing how to assess is an important issue in STEM education. From Gao et al. (2020) analysis, the studies in the assessment of integrated STEM were conducted more in informal settings (57% of the total articles) than formal settings (43% of the total articles). Within secondary and tertiary grade levels, most research was studied in secondary levels (86% of the total articles).

Diverse formats were utilized to assess STEM learning outcomes from researchers, including *questionnaire/test* (Riskowski et al., 2009; Musavi et al., 2018; Nugent et al., 2015), *interviews (individual or focus group)* (Lou et al., 2017), *observation, artifacts (e.g., worksheets, student written work) and reflections* (Dierdorp et al., 2014; Chen and Lin, 2019), *design product analyzing* (Fan and Yu, 2017), *video analysis* (English et al., 2017), etc. Also, the STEM related major application/graduate rates were considered as outcomes of STEM curriculum and programs. The most used format was questionnaire/test (76%). The second most used method was interviews (37% of the total articles) for either individual or focus group interviews. The classroom observation is also a good method to measure, particularly skills or processes of the STEM task. Some researchers tried to use video analysis of student performance for assessing STEM practices, however, this method seems impractical in the classroom assessment use due to time constraints. In addition, students' written work and design products as a result of tasks in a project have been used as evidence of student learning. Students' class artifacts such as worksheets and reflections that were completed during the process of design tasks to assess student learning formatively.

At the elementary level, considerable integrated STEM curricula and assessment have been implemented as project-based learning. For example, a project, Engineering is Elementary (EiE), developed assessment methods to measure students' understanding of engineering and technology (Cunningham et al., 2005). The assessment consisted of open-ended questions, including images of people at work, that asked about what engineers do and what technology is. This study revealed elementary students' lack of understanding about engineering, such as perception of it being male-oriented work. Other researchers also have been focused on assessing students' perceptions about the STEM disciplines or its impact on science knowledge (Apedoe et al., 2008; Brophy et al., 2008; Cunningham et al., 2005; Mehalik et al., 2008; Sadler et al., 2000).

With examples, we would like to look at assessment methods a little more closely to see how integrated STEM can be assessed at the practical classroom level. Riskowski et al. (2009) developed a design project of a practical water purification system in an eighth-grade science course, creating a table top apparatus/portable drinking water device to purify a contaminated water sample. In this study, students (1) worked in small groups and student interaction and participation were considered as a significant component of the project, (2) developed a design artifact which was considered as being reflected their understanding of water quality concepts and (3) shared their findings through a presentation with the entire class and peers were encouraged to discuss advantages and disadvantages of others' designs. These students were assessed through questionnaires multiple times in the process of the project which can be used as good examples of assessment tools using questionnaires in practical classroom use. The researchers conducted a pre/post-test including (1) true/false questions on water quality, (2) open-ended questions on how students view water quality issues in the US and (3) design questions requiring students to describe and explain their designed devices. The design question is as follows: "IDENTIFY what makes the water unsafe to drink and EXPLAIN how your design ensures safe drinking water. Use any means necessary to explain your answer, such as drawings, maps, or sentences" (p. 187). The authors presented the grading rubric and sample response for their analysis which can be used for practical assessment rubric in the classroom as well. The highest score was 4 (0–4 scale) for "Student identifies all 3 contaminants. Uses evidence to justify and explain design." (p. 187). The questionnaires can be effective when they require students' explanation and reasoning. In this study, the authors didn't include the evaluation of the design product as a data source, but the assessment of the design product can be used as an assessment tool as well. In Fan and Yu (2017)'s study, student generated design products (designing a mechanical toy) were assessed. The design products were assessed focused on functionality, mechanical design, and materials used in the design through a five-point scale. Kim and Oliver (2018) developed a water purifier design activity in a preservice teacher education program to guide how to implement and assess student generated water purifiers focused on modeling practice. The study showed the products can be assessed the aspect of functionality, designing with limited materials efficiently as well as the process of the design with modeling on the relationship among degree of purification, water flow rate and the grain size of activated charcoal through a form of drawing and writing of reasoning of the relationship of the factors.

Various approaches can be adopted for assessing student learning outcomes in integrated STEM education. Although we believe that research on assessment of integrated STEM learning can guide the development of effective and practical assessment methods to measure students' learning gains, developing the assessment tools highlighting the benefits of integrated STEM education still remains as challenges. For example, how can we answer our questions such as "what would be the best way to measure students' inter- or multi-disciplinary knowledge/skills/processes in a practical classroom STEM project? What methods can be adopted as formative and summative assessment to give valuable feedback to students in the integrated STEM?" Yet, we need much further investigations in this area.

STEM assessment and teacher education

STEM Integration in K-12 Education: Status, Prospects, and an Agenda for Research (NAE and NRC, 2014) suggested “increased STEM content and pedagogical content knowledge (PCK)” and “changes in practice” as goals and outcomes for educators. How teachers understand the integrated STEM curricula and implement STEM instructions effectively is significant for students’ successful STEM learning. In our educational system, as teachers are the most basic and pivotal resource in STEM learning, enhancing teacher’s PCK to teach integrated STEM is critical (Bybee, 2014). In turn, the integrated STEM approach requires new professional development opportunities for both in-service and pre-service teachers, and changes in teacher preparation programs. As a component of PCK, teachers’ knowledge of assessment includes knowledge of student learning as well as knowledge of assessment methods (Tamir, 1988; Park and Oliver, 2008a,b; Sun and Strobel, 2014). A few studies have shown that when teachers encountered assessment difficulties due to unfamiliar subject matter, they employed different assessment methods for two purposes: to know their students’ understanding and learning needs and to encourage and improve their students’ learning (Park and Oliver, 2008a; Sun and Strobel, 2014). The elementary teachers who participated in professional development (PD) programs for practicing engineering teaching had difficulties assessing students’ engineering learning using traditional tools such as rubrics or questions (Sun and Strobel, 2014). After trying traditional/formal assessment methods, the teachers employed different informal assessment methods in their engineering teaching such as questioning, journals, observations, or flow maps. The teachers’ usage of the different assessment methods depended on the assessment purposes. For example, some teachers asked their students to create their own criteria for assessing their engineering products in order to encourage their students to focus on the learning goals. The teachers developed knowledge of assessment through teaching practices within the specific teaching context (Kim, 2019).

How researchers have conceptualized the integrated STEM, and developed and implemented curriculum are important to better understand the assessment of the integrated STEM learning outcomes in alignment with the learning goals. In the next section, we will discuss the tensions that exist in the school level implementation of the integrated STEM and propose a conceptual model of the integrated STEM curriculum which can guide assessment of STEM.

A conceptual model for integrated STEM

If we agree that at its most fundamental core, STEM is about the integration of four domains, then successful STEM pedagogy must be conceptualized as consonant with deep approaches to learning. Although there is a great challenge that arises from the effort to prepare instructional sessions that support learning of all students in a deep manner, the greater challenge comes from preparing the assessments that will validly measure the integrated outcomes.

We want to highlight tensions that exist in school-based implementations of STEM, and propose that a new model of STEM education should be adopted such that the *Integration* of science, technology, engineering and mathematics is the primary descriptor of STEM and that each of these four areas should play an equal role in its characterization. The implication of the goals for STEM with its fully integrated and equilibrated design suggest a series of tensions that are suggested in the day to day life of science teachers and the schools in which they live. In Fig. 1, we have identified these tensions such that a tension is defined in terms of a metaphor of pulling forces that are exerted between two end-points of an argument. We are attempting to create a dialectic so as to contrast these end-points. The new STEM model considers each of the tensions and their impact on the courses that students take.

The traditional conceptualization of STEM has science at the center of all classroom activities and the other areas (technology, mathematics and engineering) feeding into it from outside or being fed by science. However, the new conceptualization of STEM puts science on an equitable footing with the other areas and integrated STEM as the instructional outcomes that arise from the integration of the four S-T-E-M units. In this new conceptualization, each of the four domains (S-T-E-M) can serve the instructional goals as one of three spaces for the construction of objectives or the enactment of teaching. These new spaces are: (1) as subject matter content; (2) as enabler of learning activities; and (3) as conceptual workspace in which the new learning can happen (See Fig. 2). This model allows each of STEM disciplines to serve as content and supports students to construct knowledge rather than just use contextualized examples. It is most easily understood how each of the four domains may be a subject matter content area; the other two functions are more abstract. Mathematics or technology, in very different ways, illustrate the “enabler” function. Frequently, students use technology as a component of the learning process, but in most cases, the technology is simply serving an instrumental function that allows the work to happen. This function is different in this model from the “workspace” in which the domain acts as a space within which the students construct the STEM knowledge. For instance, the difference might be clarified by comparing how mathematics serves to *enable* the learner to calculate values related to understanding Newton’s Laws of motion. No goal for new mathematics learning is necessarily present. In a laboratory inquiry setting, science may serve as a workspace by allowing students to learn about mathematics by creating a subject matter context in which learning takes place. In this situation, learning about both mathematics and science would be anticipated. Computer programming within the domain of technology might also have this function and serve as a workspace rather than as just an enabler. When serving as an enabler, the domain’s activity is that of a metaphorical catalyst left unchanged by the learning activity. When serving as a workspace, the domain is the site of integration of the four S-T-E-M domains into this new integrated knowledge. Throughout this conception of STEM pedagogy, each of the four domains may serve as subject matter content (Kim et al., 2016).

Fig. 1 Tensions that exist along 5 dimensions of school-based implementations of STEM. Adapted from Kim et al. (2016).

Fig. 2 Schematic representation of a new model for STEM emphasizing a multidimensional, reciprocal, and symmetric relationship between the four domains. Adapted from Kim et al. (2016).

The new STEM model is aligned with conducting assessments based on the SOLO Taxonomy that accounts for the higher-level learning outcomes and student interest and motivation. SOLO is an acronym that stands for *Structure Observation of Learning Outcomes* (Biggs and Collis, 1982). Over several decades, researchers in science education and other areas have been developing and evaluating assessments using the SOLO Taxonomy framework (Hodges and Harvey, 2003; Minogue and Jones, 2009; Padiotis and Mikropoulos, 2010). The framework identifies student outcomes using an ordinal series that begins with the lowest level of accomplishment, i.e., unistructural, to the highest, i.e., extended abstract. The advantage of using this type of framework within which to create assessments and to evaluate open-ended responses can be seen in the article by Minogue and Jones (2009). They wrote of how the challenge to students of cellular biology is magnified if they are unable to integrate

the relationship of the cell structures and the functions. This type of integration is the hallmark of STEM and of the NGSS, and thus must be assessed by tools whose potential to attribute complex and deep responses to student knowledge has demonstrable validity (Kim et al., 2016).

The existence of STEM as a revised or modified type of science course will likely not be adequate to accomplish the goals of STEM as described in either STEM-related scholarship or national reform documents. The existence of tensions such as those identified in Fig. 1 pose very real constraints on the courses currently taught in schools. But it is possible to conceive of a STEM course that would go beyond those constraints and allow the four disciplines to have an equal footing. The model presented here is a first effort to consider how that equal footing and STEM as it is often conceptualized in the scholarship of our field might be pushed into existence.

Conclusion

In this article, we reviewed ways in which integrated STEM has been conceptualized and how integrated STEM curriculum and assessment have developed to this point. Also, we discussed the current status of research on integrated STEM assessment and teachers' professional development in relation to teaching and assessment of integrated STEM. The literature on the assessment of STEM learning outcomes reveals several barriers and challenges. Based on the review, we discuss some implications on teacher education and make suggestions to help our educational community advance integrated STEM education and assessment as follows:

- In relation to the integrated STEM learning goals and outcomes as described in the *STEM Integration in K-12 Education: Status, Prospects, and an Agenda for Research* (NAE and NRC, 2014), the ability to make connections among STEM disciplines and understand the type of STEM connections are clearly stated as learning outcomes. However, there have been challenges in assessing multidisciplinary learning and the key connections among STEM disciplines to be assessed.
- Most STEM educational programs stated the orientations of their curriculum as integrated approaches to improve students' understanding of connections and multidisciplinary content knowledge and skills, however, rare are the attempts, as recorded in the research literature, to fulfill the assessment goals. As Gao et al. (2020) showed, though the stated focus of assessment is on integrated STEM, assessment of students' content or affective gains are conducted within individual disciplines even though many cases of STEM instructions were implemented in an integrated way. Also, there are few attempts to give students the opportunity to understand the connections between STEM disciplines explicitly and measure those metacognitive learning on the nature of connections among STEM disciplines (Wengrowicz et al., 2018).
- Moore et al. (2014b) clearly emphasized the practices in the process of integrated STEM curriculum (e.g., redesign or modification opportunity in engineering design) as well as social aspects such as teamwork and communication as important curriculum design components. There is little research or conceptual framework on how to assess practices/processes in STEM learning. In the same vein, there have been challenges in assessing teamwork/communication and collaborative problem solving in STEM education with concrete models and practical standards and/or rubrics.
- On a practical level, developing assessment tools and rubrics to guide school teachers for integrated STEM learning has been a critical issue. In particular, the assessment instruments and rubrics on integration are rarely developed due to the attention to the assessment of specific concepts and procedures have been paid in research and practice (NRC, 2014). Many project-based STEM learning approaches may end up with school-based projects with emphasis on student engagement but with limited assessment opportunities to measure important learning goals in STEM education.
- The integrated STEM learning can be measured as formative and summative assessment (NRC, 2014) in both formal and informal ways in relation to the curriculum development, course sequence or designing tasks with tangible learning outcomes. Teachers should be able to utilize the formative assessment in their projects and classroom lessons which enables teachers to characterize current student understanding and skills in relation to the integrated STEM learning objectives. Thus, the formative assessment information can be used to tailor and improve integrated STEM instruction (Heritage, 2013; Wiliam, 2011). However, many pre-service and in-service teachers need support on how to use diverse purposes and forms of assessment such as observations, video analysis or reflections of the integrated STEM learning practices as needed.
- Current teacher education has been considered as insufficient for ensuring teachers' readiness for teaching and assessing the integrated STEM in classrooms (Shernoff et al., 2017). This highlights that teachers need support the opportunities to be engaged in learning experiences to develop teacher knowledge and practices in STEM teaching, in particular, integrated STEM PCK which comprehensively includes orientations to teaching STEM integrated ways, knowledge of STEM curriculum, knowledge of instructional strategies, knowledge of assessment of integrated STEM and knowledge of student understanding when they are engaged in STEM curriculum (e.g., strengths and difficulties in STEM project) (Adapted from Park and Oliver, 2008a,b; Van Driel et al., 2001).
- The development of an integrated STEM curriculum should lead to the application of core concepts from multiple disciplines and STEM practices. Teachers should give students the opportunity to demonstrate their ability to design and perform STEM tasks in problem-solving or projects. In this way, students can develop a deeper understanding of the whole process of the STEM practices, and teachers should base their assessment on the tangible products students create through implementing such innovative tasks.

- Finally, the researchers found that integrated STEM learning and assessment are still fairly new initiatives and the field must continue to strive for a clearer picture of it, thus, the readiness of teachers, administrators and even students still needs support in many ways. The current status of teacher education highlights the challenges with misalignment among curricular development, teachers and administrators' understanding of STEM in implementation and assessment at schools and classroom levels. Still the attention to large-scale tests with multiple-choice items have been paid by administrators dominantly, which cannot be adequate for assessing critical thinking and creativity.

To achieve students' anticipated learning outcomes in the integrated STEM learning, appropriate assessment models and techniques that validly demonstrate the powerful learning gains resulting from this integrated approach are of great importance. It is clear that if there are no evaluation results that show the potential for validly measuring student achievement, the reform cannot move forward. This lack is compounded by the difficulty of assuring teachers of the value of innovative STEM curriculum and instructional strategies. It is essential to provide specific ways to assess student outcomes that are direct results of the implementation of STEM teaching and learning approaches to give valuable feedback to students, as well as support the professional development of teachers to enhance PCK in integrated STEM.

With ongoing demand for expertise in science, technology, engineering, and mathematics (STEM), recent educational reforms in the United States and around the world have called for improved STEM education (e.g., [Australian Curriculum, Assessment, and Reporting Authority, 2016](#); [European Commission, 2015](#); [Hong, 2017](#); [National Research Council \[NRC\], 2011](#); [NRC, 2012](#)). In addition to the need for workers within STEM fields, scientific and technological literacy are increasingly recognized as paramount to informed decision-making for all individuals living in the 21st century ([NRC, 2011](#)). Thus, providing quality STEM learning opportunities to all students, regardless of whether they intend to pursue STEM careers, is a priority in education.

Affect is significant with respect to STEM learning because of the links to learning and behavior (e.g., [Bandura, 1997](#); [Dweck and Leggett, 1988](#); [Koballa and Glynn, 2007](#); [Pintrich et al., 1993](#)). Affective learning includes feelings, emotions, attitudes, interest, self-efficacy, motivation, and identity (e.g., [Ellis and Fouts, 1996](#); [English and English, 1958](#); [Krathwohl et al., 1964](#); [Tytler, 2014](#)). A wide range of instruments have been developed to measure affective learning in STEM; however, with a range of different affective constructs, disciplinary foci, target age groups, and quality of instrumentation, selecting an appropriate instrument for a particular study can be challenging. In addition, because the validity and reliability of an instrument should be reestablished when the instrument is modified or used with a new population ([Koballa and Glynn, 2007](#)), selecting an appropriate instrument is further complicated. This article presents a systematic review of existing instruments that aim to measure affective learning across STEM domains among students in elementary through postsecondary contexts. We aim to provide researchers with a broad range of instruments, including modifications and translations, that will be useful to an international audience of researchers.

Affective learning

Affect has long been considered in relation to learning but has been challenging to define. A number of communities of researchers and practitioners, from psychology to engineering, are interested in the topic of affective learning, resulting in a lack of consistent terminology or theory related to affect in learning ([Meredith et al., 1997](#); [Tytler, 2014](#)). [Krathwohl et al. \(1964\)](#) identified three domains of learning objectives in education: cognitive, affective, and psychomotor. They defined the affective domain as emphasizing “a feeling or tone, an emotion, or a degree of acceptance or rejection” (p. 7). [English and English \(1958\)](#) defined affect as relating to a “feeling, emotion, mood, [or] temperament” (p. 15). [Ellis and Fouts \(1996\)](#) expanded these definitions to include the consideration of attitudes. Because attitudes are feelings that are shaped and endure over time rather than fleeting emotions ([McLeod, 1992](#); [Petty and Cacioppo, 1981](#)), they may hold greater potential to influence motivation, behavior, and learning. Within STEM disciplines, affective learning can be further narrowed and defined. For example, [Tytler \(2014\)](#) identified the following constructs that are central to science education: (a) attitudes toward science, scientists, and school science (b) interest in science and science-related activities or careers (c) self-efficacy in science, and (d) motivation to do and learn science.

Despite a lack of consensus in defining affective learning, it is largely accepted as an important aspect of learning. Attitudes, interests, and beliefs are known to influence students’ thinking, motivation, and behavior (e.g., [Bandura, 1997](#); [Dweck and Leggett, 1988](#); [Koballa and Glynn, 2007](#)). For example, [Pintrich et al. \(1993\)](#) found that attitudinal and motivational constructs moderated learners’ conceptual change in science, thereby influencing science learning outcomes. Personal interest has a greater influence on high school and college students’ career choices than both earning potential and parental influence ([Hall et al., 2011](#)). Interest is a more significant predictor of enrollment in STEM courses than either prior enrollment or achievement in science or mathematics

(Maltese and Tai, 2011) and heavily influences persistence in STEM (Maltese and Cooper, 2017). Guided by Tytler's framing of these constructs and our own prior research (e.g., Dare and Roehrig, 2016, 2020; Smith-Colin and Wieselmann, 2020; Wieselmann et al., 2020a,b), this systematic review of instruments that measure STEM affective learning focuses on attitudes, self-efficacy, interest, and motivation. In addition, we consider identity, or a person's conception of self that is formed through practice and impacted by social setting, power, privilege, and oppression (Calabrese Barton et al., 2013), as central to affective learning.

Methods

We structured our systematic review based on Newman and Gough (2020) recommendations. First, we developed our research question: What instruments developed between 1995 and 2020 measure STEM affective learning among students in K-16 contexts and provide psychometric evidence of reliability and validity? Second, we defined our inclusion criteria:

- Published between 1995 and 2020
- Focus on preK-16 students
- Focus on STEM (one or more disciplines)
- Focus on one or more of the following constructs: attitudes, self-efficacy, interest, motivation, and identity
- Reports on the development of an original survey (not using existing instrument solely for research purposes)
- Provides some evidence of statistical validity and reliability
- Focus is not specific to a particular intervention or course
- Published in a peer-reviewed academic journal
- Article published in English (instrument in another language okay)

With these inclusion criteria in mind, we developed our search strategy and carried out the search in September 2020. We searched three electronic databases: EBSCO Education Source, APA PsychInfo, and Education resources Information Center (ERIC). Several combinations of search terms were tested in preparation for the final search. The search terms that yielded the most relevant results are shown in Table 1. In addition to these search terms, we used the search functions to limit publication dates to 1995-present and restrict search results to publications in peer-reviewed academic journals.

With the resulting publications, we conducted several rounds of review, coding, and analysis of the studies (see Fig. 1). We initially screened the titles and abstracts to determine if they still fit within our inclusion criteria. The full texts were located and downloaded for all publications that appeared to fit our inclusion criteria. Each publication was examined in more depth for adherence to our inclusion criteria and a critical appraisal of their quality (Petticrew and Roberts, 2006). Our critical appraisal focused on two key evidence standards, identified by Gough et al. (2019). First, we considered the suitability of method. In response to critiques of attitudes instruments (e.g., Munby, 1982, 1983), Kind et al. (2007) developed guidelines for the construction of attitudes measures. These guidelines are also useful when considering the development of other affective instruments and include having a strong theoretical grounding with clear descriptions of constructs, demonstrating reliability by confirming the internal consistency of the construct (e.g., using Cronbach's alpha), providing validity evidence using multiple methods, including psychometric analyses, and taking care when combining separate constructs to form a single scale (Kind et al., 2007). With these guidelines framing our review, we paid careful attention to whether the authors of each study reported psychometric properties to provide some evidence of reliability and validity for their instrument.

In order to determine the validity of an instrument, it is necessary to consider the full range of evidence presented by the authors and whether this evidence supports the intended interpretation of a score for a certain purpose (American Educational Research Association, American Psychological Association and National Council on Measurement in Education, 2014). Researchers (e.g., Messick, 1989; Osterlind, 2006) have highlighted the importance of content, construct, and criterion validity. Content validity refers to whether the instrument represents all relevant aspects of the construct it intends to measure. Construct validity refers to whether an instrument represents the construct intended to be measured, including alignment to relevant theory and theoretical expectations. All of the studies that met our inclusion criteria relied on theory or prior instrumentation to some degree in creating the current instrument, demonstrating some level of construct validity. In addition, two particular types of construct validity were considered. First, convergent validity refers to the correlation between scores on the current instrument and scores on similar

Table 1 Search terms used for database search.

Search term	Location

Fig. 1 Search process.

instruments. Second, divergent or discriminant validity involves looking for the absence of a correlation between the current instrument and another, conceptually unrelated, instrument. Criterion validity refers to how closely the current instrument relates to another standard of comparison and includes two types. First, concurrent validity involves comparing scores on the current instrument to scores on another established instrument administered around the same time. Second, predictive validity involves comparing scores on the current instrument to some later outcome or measure to determine whether the instrument has predictive value. Face validity is sometimes used to establish the validity of an instrument, but because it is related to the *appearance* of the instrument as appropriate for measuring the construct rather than psychometric evidence, we did not consider face validity alone as sufficient validity evidence (Munby, 1982). We looked for psychometric evidence, such as exploratory factor analysis (EFA), confirmatory factor analysis (CFA), Rasch analysis, principal component analysis (PCA), and other statistics in determining whether an instrument met our inclusion criteria.

Our second key quality evidence standard, identified by Gough et al. (2019), involved examining the instrument's relevance to our research question. In particular, we ensured that the instrument was STEM-focused, excluding broader instruments that focused on things like students' general motivation to learn. We examined the instrument's relevance across contexts and excluded any instruments that were tightly linked to a particular intervention or course. We also ensured that the instrument was aligned to one or more of the five affective constructs within the scope of this study: attitudes, self-efficacy, interest, motivation, and identity.

We extracted information about each instrument that met all inclusion criteria following this deeper review of the full publication. This information included the instrument name, authors, relevant STEM discipline(s), affective construct(s) measured, grade band(s) of intended use, country(ies) of students included in the development of the instrument, including its validation studies, and the reliability and validity information that was reported.

The information extraction process revealed that some of the publications our search produced used or referenced previously published instruments, so we followed the citations back to the original sources of the instruments, using a process of historical propagation to help minimize the likelihood that our search criteria and process overlooked key instruments. In examining the sources of the original instruments, we maintained all of our inclusion criteria, with two exceptions. First, if an instrument was originally published prior to 1995 but was revalidated or underwent validity tests due to modifications (e.g., translations to another language, short form, etc.) between 1995 and 2020, it was included in our findings. Second, the Pupils' Attitudes Toward Technology (PATT) instrument (Raat and de Vries, 1986) was not originally published in a peer-reviewed journal. However, because of its prevalent use in countries around the world, future validation studies that were published in journals, and the relatively low number of instruments focused on technology, this particular instrument was included in our findings.

With our search process complete, we verified the information that had been entered about each relevant instrument. Each instrument was verified by a member of the research team who had not originally entered the instrument's information. Finally, we synthesized the results of our search to answer our research question.

Search results and discussion of constructs

Our systematic review process resulted in a total of 93 distinct instruments that measure STEM affective learning and met our inclusion criteria. A total of 44 instruments included attitudes as one of the primary affective constructs measured. Twenty of the instruments focused on self-efficacy, 12 on interest, 11 on motivation, and 10 on identity. These instruments are presented in the following sections, organized by the key constructs our review focused on: attitudes, self-efficacy, interest, motivation, and identity. It is important to note that three of the instruments focused on more than one of our focus constructs and are therefore included in multiple tables. Many of the instruments also included additional affective constructs as factors or sub-scales or considered other aspects of affect as constituent of the broader construct being measured; instruments are reported in the table or tables that most closely align with the overall focus of the instrument. Each table is organized first by STEM discipline, then alphabetically by author(s). Instruments that focus on multiple disciplines or STEM are located at the bottom of the tables. Additional publications that utilized or modified the existing instruments are included as separate columns within the row for the original instrument.

Attitudes

Research on student attitudes related to science and mathematics dates back over 50 years. The vast majority of instruments assess student attitudes toward science or mathematics; however, also present in the literature are instruments that measure scientific attitudes (e.g., Moore and Sutman, 1970) and attitudes about learning science or mathematics (e.g., Adams et al., 2006). Our search resulted in 44 instruments focused on attitudes, shown in Table 2.

Broadly, attitudes refer to a favorable or unfavorable feeling toward something and are composed of three elements: cognitive or evaluative beliefs, affective feelings and emotions, and behavioral action tendencies (Cheung, 2009; McGuire, 1985). While some attitudes instruments reside completely within the affective domain, most attitudes surveys address both affective and behavioral components because the primary goal of attitudes research is often to predict student behavior (e.g., Koballa, 1988; Osborne et al., 2003). Researchers with a strong theoretical grounding for their instrument development (e.g., Abd-El-Khalick et al., 2015; Summers and Abd-El-Khalick, 2018; Teo and Noyes, 2008) used theories of reasoned action (Ajzen and Fishbein, 1980) and, more recently, theories of reasoned action and planned behavior (Ajzen and Fishbein, 2005) to argue for the inclusion of career-oriented items.

^aInstrument was not clearly named in the publication.

^bAdditional affective measures are included as sub-scales or as part of broader constructs being measured.

^cInstrument included in another of the tables in this article because it addresses additional constructs.

Researchers agree that attitude is a complex and multi-dimensional construct, which is reflected in the development of instruments with multiple scales. Common dimensions of attitudes included enjoyment, confidence, importance or relevance, and usefulness (e.g., Bauer, 2008; Chin and Lim, 2016; Fraser, 1978; Gogolin and Schwartz, 1992; Ozcan and Koca, 2020; Tapia and Marsh, 2004; Teo and Noyes, 2008; Zhang and Campbell, 2011). However, additional dimensions are present in different attitude instruments, such as perception of the teacher, anxiety, and attitudes toward scientific inquiry and other pedagogical approaches (e.g., Adams et al., 2006; Bauer, 2008; Chin and Lim, 2016; Gogolin and Schwartz, 1992; Nadirova and Burger, 2008; Tapia and Marsh, 2004; Zhang and Campbell, 2011).

A common critique of attitudes instruments is that most researchers do not provide well-defined theoretical frameworks and definitions of constructs (e.g., Munby, 1982; Summers and Abd-El-Khalick, 2018). Thus, the construct of attitudes remains “somewhat nebulous and may be defined or framed in different ways depending on the purpose and perspective of the researcher(s) involved” (Summers and Abd-El-Khalick, 2018, p. 179). As such, a seemingly common factor like “usefulness” could focus on the usefulness or value of science to society, or alternatively, on the usefulness of science to individuals for their future careers.

In addition, concerns about theoretical grounding and definition of constructs are more complicated when considering the development of an instrument to measure attitudes toward STEM. None of the included papers that proposed a STEM attitudes instrument defined STEM. Further, proposed instruments often simply measured the same set of items separately for each discipline, and the treatment of technology differed across instruments. For example, it was sometimes assessed separately and other times included as part of a single scale with engineering.

Self-efficacy

Self-efficacy refers to individuals’ beliefs about their personal capability in a domain, and such beliefs are closely linked to what individuals believe to be the likely outcomes of their actions (Bandura, 1977). Our systematic review resulted in 20 instruments that focused on self-efficacy, shown in Table 3. Looking across STEM self-efficacy instruments, researchers relied upon common theoretical frameworks as they operationalized self-efficacy, consistently drawing upon Bandura’s self-efficacy theory. In particular, Bandura (1997) proposed four sources that influence self-efficacy beliefs: enactive mastery experiences, vicarious experiences, verbal persuasion, and affective states. Some researchers (e.g., Byars-Winston et al., 2016; Lent et al., 1991; Usher and Pajares, 2009) used these sources of self-efficacy beliefs to develop survey sub-scales or items.

In addition to Bandura’s self-efficacy theory, instruments often were framed based on Bandura’s (1986) social cognitive theory (e.g., Ibrahim et al., 2016; Lent et al., 1991; Usher and Pajares, 2009) or social cognitive career theory (SCCT; e.g., Byars-Winston et al., 2016; Hiller and Kitsantas, 2016; Nugent et al., 2015). SCCT considers how self-efficacy, outcome expectations, contextual supports and barriers, and personal inputs interact to influence academic and career interests and choices (Lent et al., 1994).

Bandura (1997, 2006) posited that self-efficacy is multi-dimensional and domain-specific. Thus, a general self-efficacy instrument is not sufficient, and researchers have developed instruments for a variety of contexts ranging in degree of specificity. For example, within science, there are instruments that aim to measure self-efficacy within the general discipline of science (e.g., Byars-Winston et al., 2016; Lin et al., 2013; Lin and Tsai, 2013), the field of biology (Baldwin et al., 1999), and specifically in relation to citizen science experiences (Hiller and Kitsantas, 2016). Within technology, instruments tended to be highly task-specific, for example, exploring self-efficacy in human-robot-interactions (Rosenthal-Von Der Pütten and Bock, 2018) and in computer programming (Tsai et al., 2019). The relative lack of instruments as well as the high degree of specificity of those measuring self-efficacy in technology aligns with ongoing debate about defining technology within the context of STEM education (e.g., Ellis et al., 2020). Therefore, researchers who hope to use an existing self-efficacy instrument will need to consider the domain of interest and whether existing options are an adequate fit given their research focus. Notably, only one of the instruments that resulted from this systematic review (Chamberlin and Powers, 2013) included elementary students as part of the intended audience, demonstrating a gap in instrumentation.

Interest

Our search resulted in 12 instruments that measure STEM interest, shown in Table 4. Looking across these instruments, two clear patterns were present in how interest was operationalized. In some cases (e.g., Lamb et al., 2012; Romine et al., 2016), the instrument was used to measure interest in the STEM discipline, nearly always including considerations of external factors that may impact interest (e.g., in-school learning, out-of-school experiences, parents, peers, etc.). These instruments were grounded in psychological underpinnings of interest development, for example, the four stages of interest development originally proposed by Hidi and Renninger (2006). Interest was also operationalized with respect to interest in STEM careers (e.g., Kier et al., 2014; Roller et al., 2020). With this in mind, these instruments tended to draw upon SCCT (Lent et al., 1994) as a theoretical framework and guide for survey factors or sub-scales. Because of this, interest in STEM was nearly always a separate factor or construct in the instrument. Although most of the latter group of instruments focused on interest in STEM careers were targeted toward older students (high school and post-secondary), this was not always the case; for example, Roller et al. (2020) leveraged SCCT to develop an instrument to examine student interest and choices in STEM careers for students in grades 4–12.

Motivation

Our systematic review resulted in 11 instruments that focused on STEM motivation, shown in [Table 5](#). Across these instruments, several theoretical frameworks were commonly used to operationalize motivation. Self-determination theory ([Deci and Ryan, 1985](#)), which distinguishes between intrinsic and extrinsic motivation and focuses on individuals' desire to fulfill fundamental needs for competence, autonomy, and relatedness, frequently served as a theoretical framework for STEM motivation instruments (e.g., [Glynn et al., 2009](#); [Hammoudi, 2020](#); [Lim and Chapman, 2015](#); [Skinner et al., 2017](#)). Additional instruments (e.g., [Glynn et al., 2009](#); [Liou and Kuo, 2014](#)) utilized social cognitive theory ([Bandura, 1986, 2001](#)), while others (e.g., [Glover and Bodzin, 2019](#); [McCormick et al., 2015](#)) used expectancy-value theory ([Eccles and Wigfield, 1995, 2002](#)). Given the connections between social cognitive theory, expectancy-value theory, and self-efficacy, it is perhaps unsurprising that self-efficacy was frequently included in the theoretical framing or as a subscale or factor in various instruments (e.g., [Glynn et al., 2009](#); [Hammoudi, 2020](#); [Liou and Kuo, 2014](#); [Tuan et al., 2005](#)). Thus, researchers who are interested in measuring self-efficacy may also find useful items or instruments in [Table 5](#). The majority of the STEM motivation instruments were focused on science and mathematics, with only one addressing technology and one addressing engineering. In addition, only two of the instruments ([Orosco, 2016](#); [Sha et al., 2015](#)), were designed for use by elementary students and two for use by middle school students ([Tuan et al., 2005](#); [Sha et al., 2015](#)).

Identity

The construct of STEM identity has notably only been studied quantitatively for the last decade or so. Our systematic review produced 10 instruments focused on measuring STEM identity, shown in [Table 6](#). These instruments primarily drew upon [Carlone and Johnson \(2007\)](#) qualitative examination of science identity, which provided a strong theoretical framework for researchers. Expectancy-value theory (e.g., [Eccles et al., 1998](#)), which emphasizes the importance of both expectations and values in shaping learning behaviors, and SCCT (e.g., [Lent et al., 1994](#)) were also used. However, the science identity framework was only adopted for science and engineering spaces; notably, mathematics and technology identity are missing from this set of instruments. Although [Dou et al. \(2019\)](#) and [Paul et al. \(2020\)](#) focus on "STEM identity," their instruments do not break down the acronym into sub-scales by discipline, but rather collapse science, technology, engineering, and mathematics into a single domain. Because the nature of identity includes interest as a main theoretical construct, interest in STEM fields (rather than in STEM careers), was included as a survey sub-scale or construct. It is interesting to note that with the exception of [Paul et al. \(2020\)](#) and [Taconis et al. \(2010\)](#), classical test theories (e.g., EFA, CFA) were used to develop the instruments, potentially due to the still exploratory nature surrounding understanding the complexity of STEM identities.

Discussion, additional considerations, and limitations

Our search results indicate the availability of a wide array of instruments that measure STEM affective learning. Of the 93 distinct instruments that measure STEM affective learning, 41 focus on science, 18 on mathematics, eight on engineering, and seven on technology. Additionally, another 19 instruments included at least two STEM disciplines, with 13 of them reporting a focus on STEM. The 13 instruments that explicitly focused on "STEM" affective learning rather than one or more of the STEM disciplines were found in relatively recent publications, the oldest of which was published in 2010, and they were also more prevalent in measuring interest than other affective constructs. The development of new, STEM-focused instruments coincides with the increasing focus on STEM education over the past decade.

Our results also explored the availability of STEM affective survey instruments across grade bands. Seventeen of the instruments were intended for use with elementary students, 37 with middle school students, 30 with high school students, and 31 with post-secondary participants. Some instruments were intended for use across multiple grade bands. Perhaps unsurprisingly given potential limitations in relation to students' reading ability, the fewest instruments existed at the lower elementary level. While some of the existing instruments were designed for use across multiple grade bands, it is important to consider the appropriateness of the instrument for the particular ages of interest and context. Those who use any existing instrument should carefully examine the items in the instrument itself rather than relying solely on the authors' recommendations for appropriate grade levels.

The instruments also measured a number of different affective constructs, with student attitudes being the most common construct, likely due to its longer history in the field of educational research. However, many of the instruments measured multiple constructs, reflecting both practical and theoretical connections among affective constructs. Three of these instruments ([Chamberlin and Powers, 2013](#); [Dalgety et al., 2003](#); [Nugent et al., 2015](#)) included two or more of the key constructs we explored as primary constructs of focus and were therefore included in multiple tables. However, there is evidence of theoretical overlap between constructs even among instruments that were placed in only one table. For example, an instrument developed based on SCCT, such as the STEM Career Interest Survey ([Kier et al., 2014](#)), may present student interest as the primary affective construct while also including items designed specifically to relate to self-efficacy, outcome expectations, and other affective constructs. The Student Interests and Motivation in Science Questionnaire (SIMSQ; [Hassan, 2008](#)) considered interest and motivation within its scales, but its overall theoretical grounding and use of existing instruments for item generation aligned more closely with the attitudes construct, so it was included in [Table 2](#).

It is also important to note that the approaches to statistical validity and reliability varied across instruments. Our inclusion criteria required some psychometric evidence of validity and reliability, but the reported studies provided different forms of

^aInstrument was not clearly named in the publication.^bAdditional affective measures are included as sub-scales or as part of broader constructs being measured.

evidence to various degrees of detail. Reliability was most frequently reported using Cronbach's alpha as a measure of internal consistency. Some publications reported test-retest reliability, with the same participants taking the survey on multiple occasions to demonstrate consistency in their responses. Validity was most often reported based on results from factor analysis (both exploratory and confirmatory). Some publications reported a Rasch analysis or convergent validity results in which participants responded to the new survey instrument as well as another, previously validated, instrument that measured the same construct to determine whether their response patterns were consistent across the different measures. Panels of experts were often used to establish validity, but particular researchers' approaches to using expert judgments varied and were reported in relation to face, content, and construct validity. In addition, the number of participants used for validation statistics varied widely across studies.

Rather than establishing clear boundaries for the amount of psychometric evidence required for the inclusion of an instrument, we included an instrument as long as it provided some psychometric evidence of both validity and reliability and met our other inclusion criteria. Thus, we highly encourage those who are considering using any of these instruments to examine the full publication and determine whether it meets their threshold of reliability and validity evidence for the intended purposes. For example, the Engineering Identity Development Scale (EIDS; Capobianco et al., 2012) has been criticized for not actually measuring identity, but rather focused on students' knowledge of engineering careers (e.g., Paul et al., 2020), so researchers aiming to measure engineering identity would be well-served to closely examine the original manuscript to determine if the construct of identity is operationalized in a manner that fits their needs. For further guidance on what should be considered when determining the validity of an instrument, we recommend consulting the *Standards for Education and Psychological Testing* chapter focused on validity (American Educational Research Association, American Psychological Association and National Council on Measurement in Education, 2014).

Although we used rigorous search procedures and carefully selected our search terms, it is important to acknowledge the limitations of this work. Despite our search of multiple databases and our consideration of references cited in the full publications we reviewed, it is possible that relevant peer-reviewed journal publications are missing from this review. However, the number of instruments presented provides a range of options for researchers in STEM education and can serve as a useful starting point in selecting a survey instrument.

We also recognize that some high-quality instruments were likely excluded from our results due to our requirement that they be published in peer-reviewed academic journals. Instruments that were published in dissertations, books, conference presentations, or other reports were not included, and these instruments may serve as additional resources for researchers or others considering STEM affective learning. For example, the Relevance of Science Education (ROSE) study (Schreiner and Sjøberg, 2004) and its associated questionnaire address student experiences and interests in science but was not included in this review. This survey is available in multiple languages and has been used in many countries around the world in international comparisons, so it may be of use to researchers. In addition, the STEM Learning and Research (STELAR) Center contains a repository of instruments that have been submitted by the National Science Foundation Innovative Technology Experiences for Students and Teachers (ITEST) projects for their research or evaluation (see <http://stelar.edc.org/resources/instruments>). This may be a useful tool for finding additional instruments aligned with particular project or research goals, but many of these instruments were not published in peer-reviewed journals.

In addition, we acknowledge that 54 of the instruments included in our results focused on students from the United States in their development. While we made every effort to include instruments developed in a diverse range of international contexts and languages, we were limited by our own language proficiencies to those that published development information, including reliability and validity details, in English. Our selection of instruments does include a number of surveys available in languages other than English, but there are certainly additional instruments that were overlooked due to this inclusion criterion. We have included citations for instrument translations that we discovered in our systematic review, but we have only reported validity and reliability evidence for the original instrument. Those who choose to use a translation should carefully examine the cited article to determine whether the instrument would be valid and reliable given the intended use.

Finally, while this review focused on quantitative measures of STEM affective learning, the limitations of a survey approach must be considered. Surveys can be an efficient means of collecting consistent data from a large number of participants, but they are inherently limited by the items included. We believe mixed methods approaches that consider complementary qualitative data (e.g., interviews, observations, etc.) in addition to quantitative survey data result in stronger research designs with a more thorough understanding of the phenomenon of STEM affective learning.

With strong connections to thinking, motivation, and behavior (e.g., Bandura, 1997; Dweck and Leggett, 1988; Koballa and Glynn, 2007; Pintrich et al., 1993), affective learning in STEM contexts is undoubtedly of great importance. Students' attitudes, self-efficacy, interest, motivation, and identity must be fostered through positive STEM learning experiences in order to work toward the goals of STEM literacy for all students as well as knowledgeable STEM workers. A vast number of survey instruments have been developed to measure STEM affective learning, and in combination with other approaches to research and evaluation, they can be used to guide the development of activities, courses, and programs that are supportive of all students' STEM affect.

Problem and objective

The goals of science education move toward developing all student knowledge-in-use (NRC, 2012; NGSS Lead States, 2013). The knowledge-in-use perspective reflects an increased awareness by learning scientists, science educators and policymakers of the proficiencies that learners will need as global citizens in the 21st Century (Choi et al., 2011; OECD, 2016) in order to address the current and emerging challenges facing our world. All learners will need to use and apply knowledge in novel ways to solve important problems and make decisions that affect their personal lives and our global society. *The Framework for K-12 Science Education* (hereafter: *The Framework*, NRC, 2012) advances this knowledge-in-use perspective of learning. Knowledge-in-use focuses on building and refining knowledge, solving problems, investigating the natural world and learning more when needed and results in deeper, more sophisticated knowledge that learners can apply. This knowledge-in-use perspective is the basis for the *Next Generation Science Standards* (NGSS) (NGSS Lead States, 2013) in the US and other national standards throughout the globe, such as the Finnish standards (Finnish National Board of Education, 2016) and German standards (Kulgemeyer and Schecker, 2014). Knowledge-in-use is also the perspective taken by PISA (OECD, 2016). With knowledge-in-use, students can develop deep, meaningful learning in which they use ideas to solve problems and make decisions by building and applying knowledge (Pellegrino and Hilton, 2012). However, how to support student equitable knowledge-in-use development with sensemaking has been a challenge in the science education field for a while (NGSS Lead States, 2013). To do that, *The Framework* and the NGSS suggest that three-dimensional (3D) learning could be one way to achieve this goal (NRC, 2012; NGSS Lead States, 2013). That is, student knowledge-in-use can be developed through using and applying knowledge in the context of three dimensions of science knowledge—science and engineering practices

(SEPs), crosscutting concepts (CCCs), and disciplinary core ideas (DCIs)—to make sense of phenomena or solve problems (NRC, 2012). With so doing, students can immerse in sensemaking process, which means they can not only connect their existing knowledge with new knowledge but can also apply what their scientific knowledge into different contexts and some new domains flexibly.

One main goal of science education is to ensure all students have the learning opportunities to learn, regardless of gender, race, ethnicity, socioeconomic status, disabilities, and English Language proficiency. To reach this inclusive goal, the performance expectations (PEs), an integration of a scientific practice, disciplinary core idea (science idea), and crosscutting concept, articulated in the NGSS are fundamental parts to support student sensemaking process and then further lead to knowledge-in-use development. The NGSS PEs promote the development of an ability to approach unfamiliar phenomena and solve complex problems with explanations and solutions. These processes involve consideration of possible viable approaches and use of a variety of science ideas and practices. A student (or a scientist) would have the capacity to sift through various ideas related to the phenomenon, for example, that could be explanatory, and ultimately, arrive at more than one acceptable explanation. In this way, the PEs, taken together, require learners to apply flexible thought. Acknowledging the range of probable and useful explanations and solutions to problems, and that there is more than one appropriate approach for each specific phenomenon or problem, is an intellectual and creative endeavor required of the next generation of scientifically literate global citizens.

Designing assessment tasks that can measure the three dimensions of scientific proficiency is a formidable task, and the field continues to struggle with how to construct assessment tasks that align with the knowledge-in-use perspective and that challenge students to solve problems and make sense of phenomena (Pellegrino and Hilton, 2012). Our vision is that assessment tasks designed with this knowledge-in-use perspective must engage learners in a complex or multi-layered phenomenon that gives rise to multiple avenues for sensemaking and affordances for using the three dimensions, similar to those in the real world. The tasks assess students' capacity to apply multiple practices, various elements of disciplinary core ideas, and several elements of crosscutting concepts as affordances for sensemaking. In this research, we explore how to construct and use knowledge-in-use assessment tasks and analyze how learners respond to such tasks.

Our work takes place in an elementary project-based learning (PBL) environment where students focus on responding to driving questions. We are developing and using knowledge-in-use assessment tasks that allow students to use multiple practices, CCCs and DCIs as tools to make sense of unfamiliar phenomena in order to promote flexible thinking, depth of knowledge, and community perspective (Pellegrino and Hilton, 2012; Baines et al., 2017; Spiro et al., 1991). We define flexible thinking as using multiple elements of DCIs, CCCs and SEPs to explain complex phenomena and examining alternative explanations for the same phenomenon (Ford and Wargo, 2012). It is important to note that to be a flexible thinker, students need to be able to access and evaluate all of the ideas that they may use to make sense of the phenomenon, and then make use of them as tools for sensemaking. Students would need to consider and discard some of the ideas as not applicable and apply others. We call this using of ideas, practices and CCCs affordances for sensemaking. We ask if this capacity can be measured, and if it can be developed over time through PBL and phenomenon-based units. Learners can draw from multiple science ideas to make sense of and explain a phenomenon (Miller et al., 2021).

Our research questions include: (1) How can we design assessment tasks that measure students' flexible use of knowledge to solicit and select from an array of the dimensions of scientific knowledge to make sense of an unfamiliar phenomenon or solve problems? and (2) How can we gather information to measure students' capacity to engage in socially situated practice of considering and weighing possible alternatives for making sense of the phenomenon under study?

Significance of work

Articulating an assessment process that will result in assessment tasks that provide robust and critical dialogic sensemaking for students and enable them to use their knowledge to think more flexibly and innovatively, closely resembling scientific and engineering endeavors. The assessment argument we present articulates a dynamic process for measuring scientific sensemaking as called for by policy documents throughout the globe (NRC, 2012; Finnish National Board of Education, 2016; Kulgemeyer and Schecker, 2014; OECD, 2016) that call for students to use their knowledge to solve problems, make decisions and think innovatively.

Knowledge-in-use goals provide new opportunities to support students in building capacity to approach unfamiliar problems and phenomena with "a developing set of ideas with explanatory possibilities" (Weick, 1995). However, assessing knowledge-in-use is challenging. This research presents one systematic method for designing assessment tasks that will engage learners in using multiple SEPs, DCIs and CCCs as affordances to make sense of complex phenomena. The tasks engage students in the figuring out process as well as gauge their depth and flexibility of knowledge, and connections to science as a social endeavor developed by and for communities.

Theoretical framework

Although policy documents from many countries describe a vision and process for learning that is situated in community and call for evaluation of a multiplicity of alternatives in science (Ford and Wargo, 2012), the interpretation of the NGSS performance expectations (PEs) in the United States for assessment purposes has focused primarily on using one SEP, an element of a DCI and a crosscutting concept. Such an approach focuses on learners applying their knowledge in a narrowly conceived area. Harris

et al. (2016) presented an approach based on the principles of evidence-centered design (ECD) (Mislevy and Haertel, 2006) to develop NGSS aligned assessment tasks for classroom use. The ECD approach emphasizes providing coherent and logical relationships among essential elements for designing assessments: (a) claims (learning goals) expressed as task performances; (b) evidence that reveals that the target learning goals are met; and (c) features of tasks that should elicit those behaviors or performances. Once these three conditions are met, this process can result in developing tasks that are highly-specific tasks, aligned to the standard or a discrete bundle of standards. The process results in evidence to support claims regarding student knowledge, and tasks to garner that information. This prior work focused on creating assessment tasks that can be used in classrooms for formative purposes and has made contributions in designing knowledge-in-use tasks. Focused on rich phenomena, these tasks assess the three dimensions of scientific proficiency—a science or engineering practice and an element of a DCI and CCC—to provide teachers with information on growth toward specific performance expectations. And while it is important to develop formative assessment tasks that can provide teachers and students with information on progress toward the standards, this work does not require learners to understand and apply multiple SEPs, elements of the DCIs and CCCs affordances to make sense of complex and novel phenomena.

We build on this prior work to design assessment tasks that better reflect knowledge-in-use including how scientists approach problems and how science is situated in the community. These assessments require learners to consider multiple scientific practices, multiple elements of DCIs and CCCs to make sense of phenomena or solve problems. Our approach builds from situated cognition and social constructivist theory of learning that propose that communities are complex systems in which the practices developed and refined within the community are responsive to the shifting goals of that community, and thus are created by and for the participants in the community (Lave and Wenger, 1991). The theory purports that sensemaking is an ongoing dialog and as such, making sense of phenomena is dynamic and messy (Miller and Januszyk, 2014). Social groups that consider and evaluate more ideas as potentially valuable have higher success rates in solving novel problems (Barron, 2003). While our curriculum resources provide goal statements that suggest specific paths for making sense of phenomena, incorporating assessment elements that reflect the *context-rich* processes of the learning allows for a more accurate portrayal of the figuring out process and thus of developing science competencies (Evans, 1999). Thus, building assessment tasks that require a multiplicity of approaches to solving the problem or making sense of a phenomenon more authentically matches the language and activities of sensemaking of STEM professionals. These assessments also provide more access to underrepresented groups such as English Learners (Moschkovich, 2007) and other underrepresented demographic groups in STEM who draw from diverse intellectual resources (Ladson-Billings, 2008; Pacheco, 2010). As students appropriate the scientific practices and science ideas, they negotiate and revise them for immediate use, a process which both improves performance and promotes a deepening understanding of what it means to “do science” (Ryu and Sandoval, 2012). Furthermore, to identify students’ strengths, we take into account how the assessment task is placed within the lived social practices of the participant and his or her interpretations of those practices (Gee, 2010; Shepard et al., 2017). As espoused in the *Framework* (NRC, 2012), to form useable understanding, knowing and doing cannot be separated, but rather must be experienced in an integrated fashion that allows for problem solving, decision making, explaining real-world phenomena, and connecting new ideas within a community of practice.

Design process

Our method for assessment development uses an iterative design-based research (Design-Based Research Collective, 2003) process in which we iteratively revise our assessment tasks based upon classroom use. Our methods for designing tasks include a seven-step process and meet three overarching objectives. We begin with unpacking in order to (1) elaborate and synthesize unit learning goals to (2) develop enduring understandings and affordances, (3) create flexible task performances, (4) design performance tasks based on related phenomena and the enduring understanding, (5) select appropriate flexible task performances and develop evidence statements, and (6) rubrics for scoring student performance tasks and evaluating test design, redesign the tasks to ensure that tasks elicit evidence of student learning, and (7) engage in iterative testing and redesign. Fig. 1 presents a schematic of the design process. The figure attempts to show the iterative and dynamic nature of the design process.

Objective 1. Elaboration and synthesis of unit learning goals (steps 1 and 2 in Fig. 1)

We first unpack and describe the array of performance expectations that students can draw from to make sense of phenomena. In unpacking we include determining the ideas that are critical for future application (knowledge-in-use) to solve problems and explain phenomena. The process involves breaking apart and expanding on the various ideas to elaborate important learning for the students at that grade level (Harris et al., 2016).

Each 6-week ML-PBL unit includes Learning Set Performances (LSP), which frame the broader three-dimensional learning goals of the unit, and provide unit coherence. Like the PEs from which they are derived, the LSPs are performance-based and engage learners in tasks to build knowledge-in-use toward PEs. The three dimensions of scientific knowledge from the LSPs stem from the initial unpacking of the NGSS performance expectations. The LSP captures more than one practice (or element of the practice), at least one DCI element, and at least one CCC element. It summarizes the LPs of the lessons in the Learning Set.

We consider the DCIs, SEPs, CCCs that make up each of the LSPs as an array of *possible affordances* for making sense of an unfamiliar phenomena. These affordances represent *the combination of experiences with the phenomenon and driving questions, and flow of the*

Fig. 1 Design process with seven steps to address three objectives.

unit, which can be represented in the Table one, below. We synthesize the elements of the LSPs and take into consideration the context of the unit to articulate an enduring understanding (Wiggins et al., 2005; Erickson, 2006) that reflects the big ideas students should take away from engaging in the unit and use to make sense of phenomena or to solve problems they encounter throughout their lives. Table 1 provides an example of the Enduring Understanding Affordances from the Squirrel Unit. The DCI elements from the LSPs are captured in the enduring understanding statement.

Evidence that students have developed knowledge-in-use of the enduring understanding is demonstrated by: *depth* of useable knowledge of affordances; *flexibility* in applying an array of DCIs, SEPs, and CCCs to make sense of phenomena; and a *robust community perspective* in which students make explicit connections to their local environment or social community.

Table 1 Enduring understanding affordances.

Practices from LSPs		Enduring understanding		CCCs from LSPs
- Observe squirrels (investigation) - Develop and revise a model - Construct claims using a model - Develop a model to explain - Analyze data from fossils - Argue from evidence - Construct claims with evidence	Using these ideas	- Species can survive hundreds of millions of years because organisms in that species are either very adaptable to changes in the environment (including changes in climate and changes in the other organisms) or because of wide diversity among them. - Generalizations: survival depends on change (adaptation). Change in the environment (over time) causes change in populations of organisms.	Using these ideas	- Systems and system models - Cause and effect - Structure and function - Stability and change - Scale, proportion and quantity - Patterns

Students use a flexible and robust array of affordances for making sense of a new but related phenomenon.

Objective 2. Creation of flexible task performance expectations, flexible performance tasks, evidence statements, and rubrics (steps 3 through 6 in Fig. 1)

While students have the opportunity to demonstrate learning connected to the phenomena throughout each unit, in the assessment, they apply an array of DCIs, SEPs, and CCCs to related but different phenomena that align to the unit driving question. The assessment phenomena must be complex and *multi-layered* (i.e., give rise to multiple avenues for sensemaking and affordances for using the three dimensions), *engaging and promoting wonderment* (i.e., student interviews show that students are motivated by the phenomena) and *related* to the unit level phenomenon (i.e., The squirrel unit is focused on looking at structures of fossils and comparing them to extant organisms, thinking about how they have changed over time to respond to needs; the related phenomenon is a change in habitat and predicting the physical response of living organisms). **Table 2** illustrates the development of related phenomenon for engagement with a new but related phenomenon in the assessment tasks.

Next, we use the phenomena to create *Flexible Task Performance Expectations (FTPE)* and *Performance Tasks*. **Fig. 2** shows an excerpt from one section of the third grade Squirrel Unit Assessment. **Figs. 3** and **4** show two more excerpts from the same assessment task.

It is important to note that the assessment offers students the opportunity to show flexible thinking and useable knowledge in more than one way. First, they may show two different DCI affordances to respond to Flexible Task Performance 1. For example a student might be able to explain how the squirrel would survive even if all the trees were cut down because they eat many different things—the idea that they are generalists (ESS3.A). Next they might be able to say that squirrels leave the area and move on (LS2.C).

Next, we point out that the students have the opportunity to demonstrate useable knowledge in the last prompt with the second new but related phenomenon. A student might use the idea that animals can adapt to changes in their environment over thousands of years (LS4.A or LS4.C).

Fig. 1 Assessment excerpt from the Squirrel Unit Assessment (chart and other text is not shown) Image attribution: Deforestation at Loch Thom <http://www.geograph.org.uk/photo/2298274>.

Each performance task is informed by the evidence of student learning: they must feature one or more practices, allow for various levels of depth and three dimensional applications for sensemaking. This means that a student could explain a phenomenon using a model, data analysis or a combination of scientific practices, and they could also draw upon the idea of adaptation, ecological systems, or animal needs for survival or a combination of these DCIs, and cause and effect, systems and systems thinking, and structure and function or combination of these CCCs to perform the figuring out.

We prompted for Robust Community Perspective with the following prompt: “How do people learn about squirrels and their changing habitats? How do you think learning about squirrels and their habitats can **help people**?”

Our aim with this question is to elicit understandings that students have developed about how science involves community-based practices, how science as an endeavor informs the community. We hope to help students build links between home,

Table 2 Develop new but related phenomenon.

Anchoring phenomenon		New but related phenomenon		
	We watch a movie that shows that a squirrel-like organisms lived at the same time as the stegosaurus and then look for squirrels and stegosaurus outside. They ask— <i>Why do I see so many squirrels but I can't find any stegosauruses?</i>	Two new but related phenomena: the squirrel's environment changes drastically. 	- Performance phenomenon must be related, rich, accurate, multi-layered and described - Performance phenomenon must be familiar, place based and accessible - Invoke wonder what will happen to the squirrel? Will it survive? What about future squirrels?	Related to anchoring phenomenon Invoke wonder —how would the squirrel population survive? Links to the DQ —the environment changes causing the squirrel to adapt to promote future species' success. The phenomenon is presented in a different context.
	Squirrel-like organisms live now and also during Jurassic.	- All the trees are cut down; - There is flooding for thousands of years and squirrels still live in the area.		

Think about Eastern Grey Squirrels and what they need from the forest.
Look at the picture on the left. If someone cuts down all the trees, what could happen to the Eastern Grey Squirrels who live in this area?
Draw a model to show what may happen to the squirrels. Make sure you show why you think that will happen. Use evidence from your experiences, the chart, and the text.

Fig. 2 Flexible performance task (FPT) 1.

You shared one idea of what could happen to the squirrels if the trees were cut down. Now, think of a very **different** idea about what might happen to the squirrels and explain your thinking.

Fig. 3 Flexible performance task (FPT) 2.

Look at the picture on Page 2 and imagine that the land flooded. Now there is so much water covering the land.

Imagine that Eastern Grey Squirrels are still living in the area after millions of years. What are possible changes you might see in Eastern Grey Squirrels that survived? How would those changes help them survive?

Write your answer and draw a picture.

Fig. 4 Cross-unit flexible performance task (FPT) 3.

community and science. For useable knowledge students need to become aware of how science practices develop over time based on local community needs (i.e., such as curiosity (Manz, 2012) or motivated by student sense-making (Berland and Hammer, 2012)). We hope to begin to elicit information regarding students' developing understanding about the relationship of scientific discovery and the larger community—scientific questions arise from community-based interests. The problems encountered by the larger community in the natural and design world inform and drive this mutual relationship. As we center all of our units in place-based and relevant driving questions, which are meant to blur the lines between classroom, home and community and science, we expect to see growth in sophistication for this question among students over time.

Objective 3. Testing and redesign of performance tasks (step 7)

We used initial evidence of student learning—for depth, flexibility and robust community perspective—to iteratively revise and refine assessment tasks based on open-ended cognitive, focus group interviews (Ginsburg, 1997) and through pre- and post-test enactment of the performance tasks during field study.

We made changes to the tasks based on the focus group interviews. While we made many revisions based on the focus groups, they were insubstantial. The majority of the changes were responding to modification in language (word use), number of lines for prompts, and readability, etc. Students reported that the tasks were “*really fun*,” and “*interesting*,” and that they would be able to “*learn from the test*” (Focus group, May 24, 2017).

Evidence of student learning incorporated both cognitive and sociocultural aspects in the following ways: (1) students make sense of phenomena using the three dimensions to guide the process, (2) students flexibly use the sensemaking tools (array of DCIs, SEPs and CCCs) for figuring out the phenomenon, and (3) students describe scientific decisions as being situated in the community, which serves as the both the motivator for science and gauge of outcomes (Zeidler et al., 2005).

Develop rubrics for depth, flexibility and robust community perspective

The rubrics were developed from our theoretical framework, appendices of the NGSS (NGSS Lead States, 2013), and an iterative analysis of the data (Miles and Huberman, 1994). Each rubric describes the (1) *depth* of three dimensional application to the task across responses to the complex task, (2) *flexibility* across at least one DCI or CCC, or two dimensions as an affordance for figuring out, and (3) reference to science as a *community*-embedded, or community-driven activity. Table 5 provides an example of the Depth Rubric. In the excerpt above (Fig. 1), students can make use of the following practices: construct and use a model to explain, analyze data, and use of evidence; elements of the DCIs of adaptation, survival in changing environments and ecological systems; and the crosscutting concepts of cause and effect, systems and system models, and structure and function.

We used the rubrics to score student responses.

Depth of knowledge

On the pre-assessment, students expressed simple ideas and were given a Depth of Knowledge designation of *Partial Affordance*. On the post-assessment, many students' responses showed depth of knowledge and flexible thinking and were given a Depth of Knowledge designation of *Quality* or *High Quality Affordance* (see Table 3). Below we provide an example of a student response on the post-unit assessment.

Table 3 Depth rubric (example).

<i>Partial affordance</i>	<i>Partial/complete affordance</i>	<i>Quality affordance</i>	<i>High quality affordance</i>
1. The squirrel will die/the squirrel will die because it needs nuts. Partial CCC cause and effect full element of EU Partial EU Partial claim	2. The squirrel will die because the squirrel meets its needs using things from the environment and the environment changes and the squirrel won't meet those needs and it will not survive. Partial CCC cause and effect full element of EU Partial claim	3. The squirrel can survive extreme circumstances (and is a generalist) and can adapt by doing something else. It will probably out a way to meet its needs. We saw that squirrels can survive on the roof of houses and eat berries. Full CCC cause and effect full element of EU Full claim	4. (As in 3, but at the species scale.) The squirrel will not only survive but it can have babies who will also survive and they will have behavior that is similar to the squirrel who survives by eating berries and living on a roof. Adds one or more dimensions to the 3D to provide depth. In this case added another element of the EU, and CCC (Scale, proportion and quantity)
1. The environment changed a lot and this impacts this squirrel. Partial CCC stability and change partial element of the EU partial claim	2. The squirrel lives in different kinds of environments over lots of years. This is because squirrels have a lot of different physical and/or behavioral characteristics. Partial CCC stability and change full element of EU partial claim	3. As the environment has changed, some animals like the squirrel have changed. As the squirrel changes over time it has become really different (like the marmot and the gray squirrel) as a response to meet its needs as a population. Full CCC stability and change full element of EU full claim	4. As in 3, but includes the idea that the squirrel also has changed the environment. Adds one or more dimensions to the 3D to provide depth. In this case added another element of the EU, CCC (systems models)

Robust community perspective

Because this performance task aims to elicit students' sensemaking of the context for science knowledge (social, environmental, historical, or any other context applied). There are three criteria for Robust Community Perspective (see [Table 4](#)).

1. Students provide evidence of community perspective for science, i.e., community from which they derived information (by referencing class or home/community, referencing text), and/or community with whom they are sharing information (by considering audience in their model and reasoning).
2. Students refer to social, critical, and historical perspectives or place and context.
3. Students include thoughts about science community and agreed-upon norms and practices.

Designed for flexibility

Students show multiple avenues of engagement using more than one element of Enduring Understanding, and CCC with practice in an answer to present possibilities or different outcomes or perspectives.

Methodology and analysis**Context and participation**

Our work is situated in upper elementary project-based learning environments ([Blumenfeld et al., 1991](#)) located within 12 school districts across two Midwestern states, in which learners make sense of phenomena or solve problems collaboratively by making use of the three dimensions of the NGSS. In the second year, the study involved 12 teachers and their classes () and the third year, 21

Table 4 Robust community perspective rubric.

2. Quality (more than one) - Mentions context of science work, as social practice, in class or society. - Indicates awareness of audience in communicating response. - Reflects that science endeavor impacts the world.	1. Moving toward (includes one) - Mentions context of science work, as social practice, in class or society. - Indicates awareness of audience in communicating response. - Reflects that science endeavor impacts the world.	0. Does not demonstrate community perspective - Missing mention of context of science work, as social context in class or society. - Missing indication of awareness of audience in response. - Missing reflection of science endeavor having impact in the world.
---	--	---

teachers and their classes. Our study presented here took part in the second and third year of the Multiple Literacies in Project-based Learning Project (ML-PBL; Krajcik et al., 2015; Miller and Krajcik, 2019) in which we designed, enacted and revised third, fourth and fifth grade project-based resources for meeting the NGSS performance expectations as well as Common Core State Standards in English Language Arts and Mathematics. Students engage in finding answers to driving questions by *collaboratively* building artifacts, which are meaningful to the classroom community, and often centered on authentic problems. Driving questions are designed to promote student engagement and student learning throughout the project. Moreover, driving questions are broad enough to allow learners to ask sub-questions and pursue solutions to those questions throughout the project. For the research reported in this paper, our work takes place in 4 of the third grade classrooms in which teachers are enacting ML-PBL units.

Participation

In this paper, we report on data from one-third grade unit: *Why do I see so many squirrels, but I can't find any stegosauruses?* The Squirrel unit focuses on adaptation, diversity, survival, fossils and extinction. In the squirrel unit, the students first observe squirrels and make a model of how squirrels survive in their environment, slowly adding ideas about specialized structures and ecological systems. Then they examine fossils and consider how fossils, specifically fossils of prehistoric rodent-like organisms provide clues about the structures and ecological systems of the Jurassic period. Finally, the students collaborate on a presentation (drawing, model, story or play) that explains how the early rodent might have survived when the stegosaurus died out.

Sample

The samples of this study come from three classrooms in years 2 and 3 of the 5-year curriculum development project. In two of the classes, the teachers were second year enactors of ML-PBL and in the third classroom, the teacher was in first year enactment. In the first classroom (second year enactment, urban), 100% of students are economically disadvantaged, and the majority of the students speak a language other than English in the home. The other two classes are situated in rural schools with a majority of white students and high poverty (<75% economically disadvantaged). The assessments in both years were given with a scripted slide presentation to reduce any confusion the students might encounter with directions, with English language and/or wording.

Data sources

Cognitive interviews. Pre and post-unit assessment

The data for this study are derived from a pre- and post-unit assessment of the Grade 3 ML-PBL Units: *Why do I see so many squirrels, but I can't find any stegosauruses?* To assure usability of the tasks, we performed two sets of semi-structured cognitive task interviews with focus groups (Ginsburg, 1997). We videotaped and transcribed eight groups of two students each, working through the tasks collaboratively. Lave describes learning as “change in participatory practice” (1991). As “individual” learning cannot be understood apart from larger social and historical influences (Gutiérrez et al., 1999), and since we hope to gain access into changes to the dialogic processes of sensemaking, we sought to understand how the students use their meaning-making resources in context, and over time change their understanding of participatory practice. Thus, semi-structured interviews provide access to the students' various resources and socially developed constructs of practices for figuring out (Barron, 2003; Carlone and Johnson, 2007) before participating in the units, and then as they become (re) negotiated over time.

The students were selected by the teacher to represent a range of science, math and language interests and proficiencies. Four of the sixteen students were English language learners. The students made sense of the tasks and orally explained their thinking, providing in-the-moment access to their thinking processes (Webb, 1982). The task was designed to indicate the process that underlies the dynamic shared learning (a shared-knowledge product) of two subjects working together to solve a problem. We transcribed the interviews to understand the learning of the two individuals working together and how their shared knowledge influences how they make sense of the task (Chi, 1997). We used these findings to revise the tasks. Table 5 presents sample questions from the semi-structured cognitive task interviews.

Finally, we tested the tasks pre- and post-unit enactment with three classrooms with approximately 18 students in each classroom. Immediately after the task, we administered four to six semi-structured interviews about the assessment task and how it felt to take the assessment. Table 6 presents several questions that were asked of students after completing the post task.

Table 5 Example of the cognitive task interview.

Q1	Please rephrase the prompt or task in your own words? Do you have any questions?
Q2	Are there any parts of this section that you find confusing? Do you have any questions?
Q3	This task asks you to _____. What do you think this means you need to do?

Table 6 Example of the semi-structured task interview.

Q1	How did that (assessment) go for you?
Q2	What did you find challenging? What did you find interesting?
Q3	Were you able to show what you know?

Data analysis

Analysis of student data

We rely on mixed methods (Creswell and Clark, 2017) emphasizing both qualitative understandings of how students use talk to organize their thinking (Silverman, 2006), and a quantitative analysis of artifacts for depth, flexibility and use of community resources. We analyzed the assessments of 60 students for depth, flexibility, and use of community resources. We examined internal and shared processes (collaborative knowledge building) through discourse, analysis of semi-structured interviews of focus groups, artifact collection, and the analysis of the assessment.

Example of student response on the squirrel post-unit assessment focus group

After introducing students to and providing information about the phenomenon (2 species of squirrels that live in different areas), and prompting students to think about similarities and differences as well as how the squirrels meet their needs, we asked the question (as in the example above): “If someone cuts down all the trees, what could happen to the Eastern Gray Squirrels who live in this area? Use evidence from your experiences, the chart, and the text.”

Focus Group students’ written responses: *The squirrel will not be able to hide and the hawks will eat them. No more squirrel will survive here. Squirrel have to have trees to hide and survive. Some squirrels will move to a new forest and live there.*

The task continued with the following prompt: “You shared one idea of what might happen. Now share of a very different idea of what could happen to the population of squirrels? Use evidence in your answer.”

Focus Group students’ written responses: *Some of the squirrels will hide in the chopped down trees and they bury the nuts and those seeds will grow into trees. The squirrels might survive because they can adapt. Some squirrels live in (student’s) attic and some can live in the rain gutter.*

Response analysis

Context

We analyzed pre- and post-unit assessments from classrooms in three school districts. We did not however help the students read the chart provided in the first part of the assessment (not pictured here). Students were given the chance to ask clarifying questions about wording, directions, and the teachers were provided instruction as to how to solicit and answer all questions equally across settings.

Evidence that students have developed knowledge-in-use of the enduring understanding is demonstrated by: *depth* of useable knowledge; *flexibility* in applying an array of DCIs, SEPs, and CCCs to make sense of phenomena; and a robust *community perspective*, in which students make explicit connections to their local environment or social community.

Depth of knowledge as evidence of knowledge in use

Based on our rubric, across the pre- and post-assessment artifacts examined for this study, the overwhelming majority of students developed in depth of knowledge as shown in the application of one Practice, CCC and element of the DCI to address the question. As indicated in Table 7, students across the three classrooms demonstrated growth in depth of knowledge.

Flexible thinking as evidence of knowledge in use

We found that students “tried on” various approaches to solving the problem or making sense of the phenomenon and that these “trying on” approaches were often, but not always, correlated with depth of knowledge. Students were able to write *different possible ideas* as a demonstration of their understanding of the affordances that different SEPs, DCIs or CCCs offer the sensemaking process, or in other words that students showed evidence of flexible thinking. Based on the focus group, cognitive interviews and field tests, we saw an increase in flexible thinking after instruction in all classrooms, but more in some than others. In the example above, the student who first suggested that the squirrels would not survive describes another possible scenario in which the squirrels plant nuts that grow into trees or that the squirrels adapt to the new environment.

In Fig. 5, we see an example of flexible thinking across questions 1 and 2 for the **same phenomenon**. The student used ideas of the environment providing needs for the animal to survive, and then approached the question again using ideas of adaptation. We see two DCI components used as affordances for sensemaking (*LS2.C Ecosystem Dynamics* and *LS4.C Adaptation*); and two different CCC’s (*structure and function* and *cause and effect* respectively) and two practices. The ideas show depth of thinking for one DCI (*LS4.D Biodiversity*), but do not use correct science ideas for a second DCI (*LS4.C Adaptation*). However, the understanding of affordance of the DCI *LS4.C Adaptation* does not correspond with evidence of depth of that idea. We noticed across the artifacts that flexibility did not always correspond with depth of DCI component, CCC or practice use.

Table 7 Growth in depth of student knowledge.

Site 1	Growth in depth 89%
Site 2	Growth in depth 88.8%
Site 3	Growth in depth 94.7%

Fig. 5 Example of flexible thinking across Q1 and 2 for the **same phenomenon**. The student used ideas of the environment providing needs for the animal to survive, and then approached the question using ideas of adaptation.

In **Fig. 6**, note an artifact from a different student from class 3, and a non-example of flexible thinking across Q1 and 2 and across the assessment tasks with two related phenomena. This student is considered to have not yet reached “flexible thinking” because s/he responded with the same DCI component (*ecosystem dynamics LS2.C*) for each of the tasks for the first phenomenon, including the prompt for flexible thinking. This is the same student responding to the new prompt related to the new (second) phenomenon (below). They use the same idea and CCC as they did for the first phenomenon. (In both cases, we prompt for the same practice.)

In the following example, **Fig. 7**, the student showed evidence of flexible thinking to make sense of the different but related phenomenon, the first where there is an immediate change to the environment, and the other where the squirrel survived in an environment with different features, over millions of years.

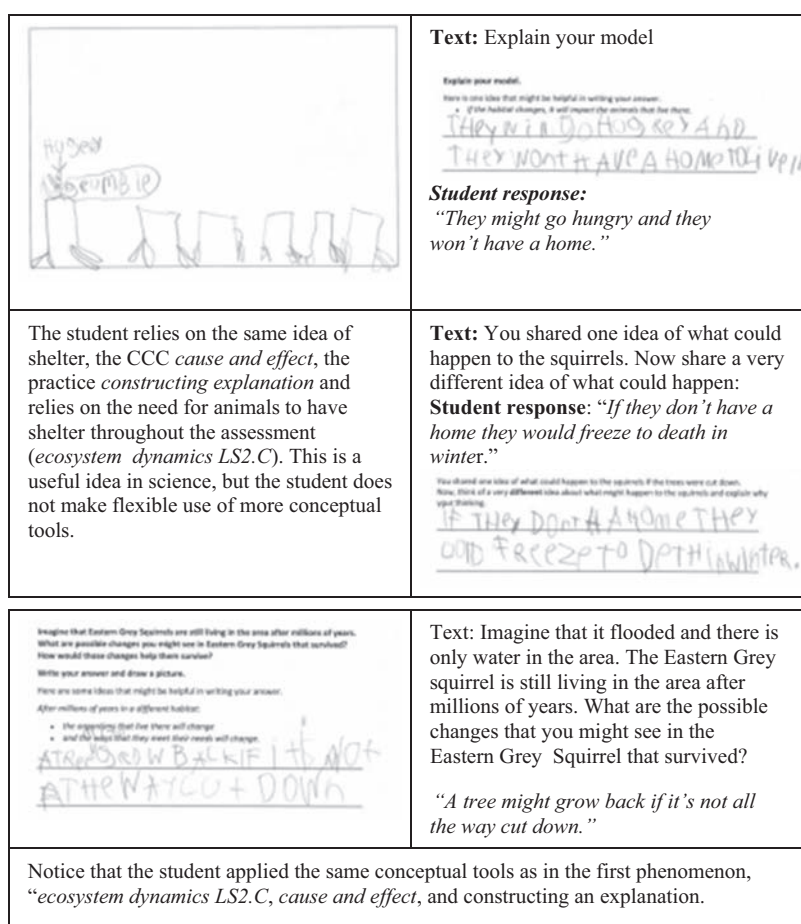

Fig. 6 Non-example of flexible thinking The same DCI component, CCC and practice (modeling is shown as prompted, but the student relied heavily on the explanation) is applied across the prompts.

Flexible Performance Task 1. First Phenomenon.  Text Prompt: All the tree are cut down in the area. What might happen to the squirrel who live there? Student Response: Model: <i>The trees are cut down and there is no food. Explanation, "They need the nuts from the trees, the squirrels might die."</i>	Flexible Performance Task 2. Second Phenomenon. Text Prompt: Imagine that it flooded and there is only water in the area. The Eastern Grey squirrel is still living in the area after millions of years. What are the possible changes that you might see in the Eastern Grey Squirrel that survived?  Student response: <i>"They could change into a miniature beaver. The body parts they would need are webbed feet, leather tail, and keep their sharp teeth."</i>
---	---

Fig. 7 Example of flexible thinking across the flexible task performances (across the different phenomena). Use of different CCC (structure and function and cause and effect respectively) and DCI across the assessment items (ecosystem dynamics LS2.C and LS4.C Adaptation respectively).

Robust community perspective

While in the focus interviews, we did not prompt specifically for community perspective, some students brought forth evidence of this understanding (i.e., "We talked about this in class, when we looked at skulls. Animals fit the place they live in" and "It's good for people to have trees"), which initiated new prompts in our redesign. Community connections were less evident in a majority of focus group interviews. As we refine these assessments, we will elicit these connections more explicitly.

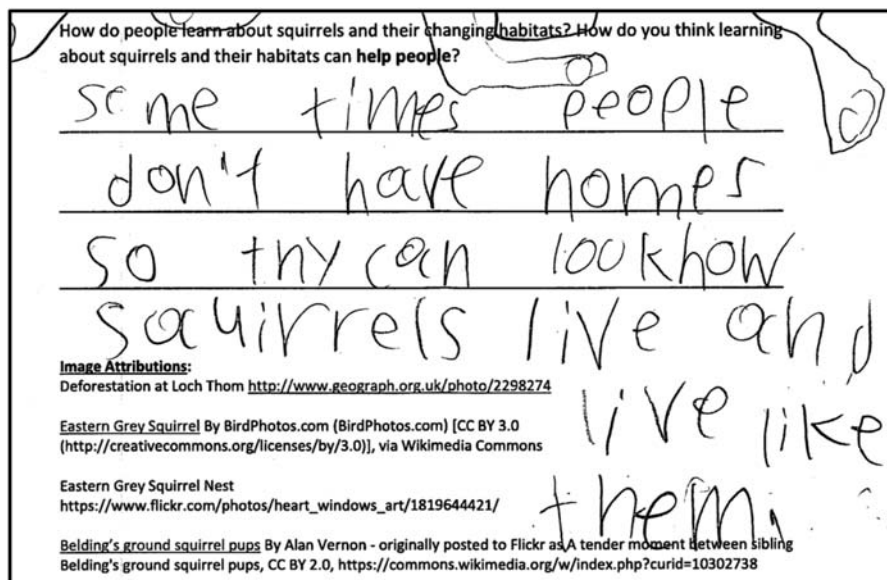

Fig. 8 shows one example of a student's response, which demonstrates full affordance of community perspective.

This example shows two items in our rubric: Mentions context of science work, as social practice, in class or society; Reflects that science endeavor impacts the world. Overall we saw that students gained in Robust Community Perspective across the classes, but they developed this criteria for Knowledge -in-Use differently.

Table 8 shows pre- and post-assessment scores on community perspective at the three sites.

Major findings

Our analysis shows that our flexible task performances can elicit depth of knowledge as evidenced by full application and flexible use of elements of the SEPs, DCIs and CCCs, to make sense of complex phenomena. In addition, they can elicit change in the three domains of depth of knowledge, flexibility in use of ideas and robust community perspective.

How do people learn about squirrels and their changing habitats? How do you think learning about squirrels and their habitats can help people?

some times people
don't have homes
so they can look how
squirrels live and
live like
them.

Fig. 8 An example of full affordance of community perspective.

Table 8 Pre and post scores on community perspective in the three sites.

Site 1	Evidence of community perspective pre 20%/post 100%
Site 2	Evidence of community perspective pre 31.8%/post 88%
Site 3	Evidence of community perspective pre 37%/post 87.5%

Flexible thinking growth data across three classes show there were students in each class who showed evidence of flexible thinking. Across the three classrooms, 59% showed some evidence of flexible thinking (Figs. 9 and 10). We also see that in one classroom, a small majority of students responded to the prompts with flexibility and one in which there was a minority of students who responded to the prompts with flexible thinking.

As seen in Fig. 9, in each classroom the majority of students developed depth of sophistication of ideas. In terms of flexibility, the amount of growth seems dependent on in class contextual factors, (i.e., such as teaching style or classroom makeup.) Most of the growth is seen as occurring in **sophistication of ideas** across the three classes.

In School 1, the majority of the students did not grow in Flexible thinking, but grew in sophistication of ideas and practices. In school 2, in contrast, the majority of the students developed in depth as well as in flexibility, and in school 3, the same number of students developed knowledge-in-use as those who did not. These data suggest that there are contextual factors that influence this growth in knowledge-in-use, and that it is not necessarily correlated to growth in sophistication of ideas.

**Fig. 9** Pie chart showing percentage of flexible thinking $n = 59$.**Fig. 10** Learners' depth of knowledge and flexible use of affordances increased over time.

Discussion and significance

Assessment of “what we can measure” informs instruction and teacher noticing (Shepard et al., 2017). We keep this in mind as we develop flexible performance tasks designed to socially meaningful context-rich project-based learning environments and to the NGSS. We integrate ideas from the practice world of scientists, with the context of PBL, and the knowledge-in-use perspective to inform teachers about what evidence of students’ learning we care about (Biesta, 2015)—depth, flexibility and community perspective. The knowledge-in-use perspective provides new opportunities to support students in building capacity to approach unfamiliar problems and complex and multi-layered phenomena using a developing set of ideas that allow them to provide explanatory possibilities (Weick, 1995). The expansive approach to assessment highlights students’ potential, particularly those with diverse intellectual and linguistic resources (see, Miller and Reigh, 2020).

However, assessing knowledge-in-use is challenging. Building on previous work (Miller et al., 2018), we develop a systematic process to the design of performance tasks that can provide evidence of depth of knowledge, flexible thinking and community perspective. These flexible performance tasks were tested in elementary classrooms using project-based materials designed to meet the performance expectation of the NGSS and the intent of the Framework for K-12 Science Teaching. Our findings demonstrate that the flexible performance tasks can elicit depth of student knowledge, flexibility in thinking, and community perspective when administered in PBL classrooms. However, based on our findings, questions emerged such as why some classrooms fostered more growth than others in knowledge-in-use, and which instructional practices and contexts promote greater development of knowledge in use. We wonder about the relationship between the richness of sensemaking discourse that happens in the classroom and the development of knowledge-in-use. Our hope is that the flexible performance tasks gather understanding of what students know, but also show an understanding that learning is inseparable from what students can perform in the PBL socially situated context with a multiplicity of perspectives and community-grounded motivators for the science work underway (Gee, 2010).

Introduction: a primer on the necessity for neuro and physiological tools

Characterizing the process of learning in STEM education is an extremely difficult undertaking and this is partly due to the myriad of knowledge types and conceptions involved in defining the field itself. Acknowledging the complexity, which characterizing learning in STEM education entails, is important to considerations of applying neurological and physiological methods in this field of research. A defining characteristic of learning in STEM education is the focus on developing capability, which is more concerned with knowledge utility, application and adaptability than acquisition (Kimbell and Stables, 2008). This focus has given rise to the notion of STEM learning as a complex adaptive system (c.f. Stephens and Richey, 2011). These systems result in emergent behavior occurring in a non-linear fashion, involving interaction between agents resulting in more complex learning than could be achieved in linear individualistic fashions (Jacobson et al., 2019).

Pertinent to this review is the concept of nested systems among CAS (Jacobson et al., 2016). A CAS can be treated as various complex systems within one another, such as the classroom environment, a group of students in a project-based learning scenario, the individual student within this group, and the individual brain of this student. If we accept this analogy as appropriate to characterizing learning in STEM, then how exactly do we achieve a complete sketch of the process of learning? For example, problem-based learning is an oft cited pedagogical approach used in many STEM contexts and across all levels of educational provision (Williams et al., 2008; Newhouse, 2016; Delahunty, 2019). Problem solving is a complex higher-level set of cognitive processes (Stillings et al., 1995) and has a significant history in psychology and educational research. Of important note stemming from this history is that the predominant research focus, in the area of problem solving in education, relates to the overt behaviors and heuristics in the process of solving problems (Ohlsson, 2012; Jakel and Schreiber, 2013). As delineated by Ohlsson (2012), this is likely due to the dominance that behaviorism exerted on educational and psychological research. An important dearth in our understanding that arises from this focus on heuristics is the tacit cognitive phenomena that underpin problem solving that are not directly observable in overt behavior or performance. To do this we need an enhanced repertoire of research methods that allow us to observe the “unobservable”.

Applications of neurocognitive methods to educational research in STEM

There are several considerations that must be addressed in the application of any neurocognitive method to research in education. Of course, it goes without saying that ethical considerations must be to the forefront of the researcher's mind. It is important to briefly delineate some core principles that must be considered by the researcher in contemplating the application of neurocognitive or physiological measures to their research. Some of these have been primary rallied in criticisms of the field of educational neuroscience in general. For example, neuromyths are often utilized to exemplify the miscommunication or misapplication between

neuroscience and education. These are defined as misunderstandings about the brain and education held among teachers or the wider public which do not stand up to scrutiny (Gardner, 2019). Another criticism that has been aimed at the role of neurocognitive data in educational contexts has to do with the “seductive allure” of neuroscience explanations (Weisberg et al., 2008). This broadly relates to the phenomenon that evidence is more likely to be believed if the presentation of it is accompanied by complex brain images. Both of these examples highlight the issue of framing the research itself and appropriately weighting the methods within the study.

Much of the framing issue with regards to research using neurocognitive methods again comes back to how learning is conceptualized as a set of processes. Howard-Jones (2011) reminds us that neuroscience and education both have distinct heritages and philosophies such as the positivist images of the controlled experiments in the neuroscience lab versus the social complexities of constructivist learning in the classroom. What is critical to remember here is that neither perspective alone can explain the totality of any learning mechanism or process and what is required is an interdisciplinary mindset to overcome the growing pains of the discipline of educational neuroscience (Thomas et al., 2019). Pragmatically, this means that the STEM education researcher does not start with the intention of utilizing a neurocognitive method but instead critically frames their research, using appropriate theory and evidence, to focus on the aspect of the learning process that they wish to investigate. Once the research questions are posed it can then be decided if the appropriate neurocognitive method is required.

In what follows I review a series of studies using appropriate alignment of neurocognitive methods for STEM educational research that sought to investigate STEM-related learning processes. It would be impossible to review a large series of studies in the space afforded here so I have tried to focus on studies that have carefully selected a neurocognitive tool with the aim of elucidating a STEM learning process typically unattainable (or attainable with great difficulty and potential bias) by direct observation. Aligning with calls for interdisciplinarity between neuroscience and education (e.g. Thomas et al., 2019; Howard-Jones, 2011), my intention is to demonstrate how a neurocognitive or physiological method can augment the typical repertoire of educational research methods. Again, given the limited space afforded in this article, I will focus on the two most popular and utilised approaches; EEG and fMRI.

Research approaches using electroencephalography

Electroencephalography (EEG) is a neuroscientific tool that measures electrical activity, generated from the cerebral cortex, through a series of sensors on the human scalp (Rowan and Tolunsky, 2003). It is a method that offers a high degree of temporal resolution allowing the accurate detection of the onset of significant behavioral events in the neurological signal recorded (Delahunty et al., 2018) often within milliseconds of the occurrence (Banich and Compton, 2011). There are a variety of EEG devices available ranging from the high-density versions associated with laboratory settings to the more recent evolution of portable wireless EEG devices (See Fig. 1).

Clearly the high-density devices have higher spatial accuracy given the increased number of sensors available to the researcher however, they are restricted to the laboratory setting.

Investigating cognitive strategies: the case of arithmetic

Core to the study of problem-solving in STEM education research is the desire to uncover evidence related to the cognitive strategies that underpin students’ performances. As discussed in other research (e.g. Delahunty, 2019; Delahunty et al., 2018), typical educational and psychological methods rely almost entirely on indirect evidence to determine evidence of these various strategies. The issue with using indirect evidence such as visual-verbal protocol or analysis of performance data is that the underlying cognitive mechanisms that led to the visible behavior or external representation remain unknown, or at the very least inferred with large potential for error. Seeking direct evidence of the cognitive bases of these problem-solving strategies is precisely where a tool such as EEG can add much value to a research project.

Hinault and Lemaire (2016) cite the case of arithmetic strategies in mathematical problem solving as an area where EEG can unpack some of the hidden underlying cognition that underpins students’ arithmetic. In particular, arithmetic reasoning episodes have short latencies and are often tacit, meaning that students will not be able to report on their approaches accurately, for example

Fig. 1 High density lab-based EEG (Left) and portable wireless EEG headset (right).

in a think aloud method (Thevenot et al., 2010). There are several arithmetic strategies commonly reported in the literature. Two common strategies are procedural (e.g. decomposing problems into smaller facts, $8 + 13$ decomposed into $8 + 3 + 10$) or retrieval (e.g. 40 for 10×4) (Hinault and Lemaire, 2016). These examples should emphasize how difficult it is to capture direct evidence of the cognitive processing occurring during such a short problem epoch.

In a study with 25 university students, Grabner and De Smedt (2011) used EEG in conjunction with verbal reports to explore the cognitive bases of arithmetic reasoning. They found that reports of the retrieval strategy were accompanied by theta band synchronization over the left parietooccipital areas of the cortex (a cortical area implicated in mathematical reasoning in adults (Cf. Wendelken, 2015)) compared to procedural strategies, which demonstrated higher levels of alpha band desynchronization in the right parietooccipital areas (ibid). Theta band frequencies are often associated with retrieval from long-term memory (Klimesch, 1999) whereas alpha dyssynchronization or decreases can reflect cognitive activation and increased cognitive load (Neubauer et al., 2006). This study by Grabner and De Smedt (2011) demonstrates that the arithmetic strategies involve distinct cognitive networks in the cortex and support the hypothesis that retrieval strategies are less cognitively demanding than procedural strategies.

Building on this evidence, research can then move on to look at the cognitive demands and strategy elicitation of task types. Take for example the idea that a teacher may want to engage students in the procedural strategy of arithmetic problem solving rather than relying on retrieval, which although cognitively less demanding, may prevent the progression of students to solving more complex tasks. How then do they know that the textbook problems will do this? This is where a research study with the neurocognitive lens of EEG may be useful. De Smedt et al. (2009) conducted such an experimental study, manipulating arithmetic problem size with a sample of university students. In this work they found that the larger problems, being logically more demanding, elicited procedural strategy use shown by desynchronization of the alpha band in bi-lateral parietooccipital areas. Zarjam et al. (2013) conducted a similar study and found increased levels of desynchronization of alpha and delta frequency bands over the frontal lobes (known seat of working memory) for the larger and more complex arithmetic problems. This desynchronization, being an indice of cognitive activation and load in the alpha band, highlights a greater demand being placed on the working memory centers. Moreover, the discernible patterns of activity and engagement dependent on the type of task, allows the researcher to evaluate these designs with high accuracy and ultimately draw out the implications for educational practices.

Lastly, moving to a longitudinal analysis of how learning and strategy use in arithmetic interact over time, Soltanlou et al. (2019) recorded EEG while children solved a series of multiplication tasks. They found that over time the students transitioned from a procedural strategy to a retrieval strategy, indicated by progressively increasing levels of theta power in successive trials. Theta band power and desynchronisation correspond to the retrieval of content from semantic memory networks (Chiang et al., 2016). Therefore we see that as students become more proficient in a particular element of mathematics, they rely less on effortful procedural cognition and more on retrieval strategies. Taken together, these studies highlight that it is possible to excise neural data on both cognitive load and strategy use with the EEG method in response to problem task design parameters. This has both utility for the STEM education researcher and practical application in the learning sciences for the design of pedagogical approaches and task materials.

Exploring individual/group differences in STEM: the case of spatial reasoning

The study of individual differences in reasoning and problem solving has led to much of our understanding as to how individuals approach their learning and how, as educators, we should direct our pedagogy to alleviate potential barriers to student progression. Perhaps the best known case of group differences in STEM education is the consistently reported sex differences in spatial cognition favoring males, particularly in mental rotation (e.g. Sorby, 2009; Casey, 2013; Halpern and Collaer, 2005). I will not belabor the relationship of spatial talent to STEM success, but these individual sex differences do help in understanding some of why female representation in STEM is generally poor. Now to the complicated part, why do females perform worse in mental rotation (MR)? There are many possible reasons for this ranging from developmental differences in the sociocultural upbringings of males and females (Sorby, 1999) to biological differences in working memory capacity (Kaufman, 2007).

Another well founded difference in males and females is in strategy use. Numerous studies report a general phenomenon of males using holistic strategies whereas females use more analytical approaches during mental rotation problems (e.g. Peña et al., 2008; Heil and Jansen-Osmann, 2008). While it is tempting to assume a neat divide in strategy preference according to gender grouping, the research on strategy types is more varied. In a study with 1695 second level students completing a MR test, Geiser et al. (2006) implemented a latent class analysis to determine 5 potential classes of strategies that were evident ranging from holistic to analytical categories. In a more recent study, Hegarty (2018) utilized the same MR tasks as Geiser and colleagues with a group of undergraduate students and collected concurrent verbal protocol data. During analysis, Hegarty (2018) found that most participants, regardless of gender, utilized a blend of holistic and analytic strategies. This suggests that the effect of strategy use in explaining sex differences in MR is complex and again there are issues evident in the use of behavioral strategies in inferring the existence of strategy differences.

How does spatial reasoning map to EEG data?

The application of EEG as an alternative lens in this particular instance of STEM education has uncovered more nuances that further our understanding of this critical issue. In mapping spatial reasoning to its neurological bases, a number of key networks and frequencies have been shown to indicate elements of spatial cognitive processing in EEG data. In particular, the desynchronization of the alpha frequency in the parietooccipital regions of the cortex is thought to be indicative of visuospatial cognition (Cabeza and Nyberg, 2000; Rescher and Rapplesberger, 1999; Klimesch, 1997).

Fig. 2 Hypothesized model of mental rotation with cortical mappings. From Gill, H.S., O'Boyle, M.W., Hathaway, J., 1998. Cortical distribution of EEG activity for component processes during mental rotation. *Cortex* 34, 707–718.

Specific to MR, which is often the spatial reasoning process associated with the majority of sex differences (Casey, 2013), Gill et al. (1998) found that MR resulted in increased alpha desynchronization in the right frontal and left parietal areas. This points to both an active encoding, maintenance, manipulation and comparison of base stimuli with target stimuli (see Fig. 2) that is achieved through functional connection of working memory and visuospatial areas of the cortex (Gill et al., 1998; Delahunty et al., 2020; Klimesch, 1999). Increased levels and duration of alpha suppression are found with increased angular disparities in MR tasks (Michel et al., 1994).

Examining sex differences with EEG methods

Coupled with strategy use, as a potential mediator of sex differences in MR, some research has found that the modality in which tasks are presented moderates this effect further. Research by Parsons (2004) found that the sex difference completely disappeared when stimuli were presented in a true 3-D format (virtual environment) compared to a paper and pencil version (2-D representations of 3-D stimuli). So, this begs the question of whether the sex difference is truly confined to MR or abstractions of rotated stimuli, especially given the malleability of MR skills (c.f. Uttal et al., 2013)? Again, a neurocognitive lens may add further clarity. Rescher and Rapplesberger (1999) were among the first to begin looking at potential differences in EEG between males and females during a MR task. They found distinct patterns of cognitive activation in males and females with males displaying more coherence in alpha band in frontal and parietal areas and females displaying more overall brain activity, especially in the posterior areas. This suggests that females have to exert significantly higher levels of activation during MR compared to males but also that a different cortical network is implicated and differentiated by sex.

In a more recent study, Gootjes et al. (2008) used EEG with a group of young adults and found a significant effect of performance and connectivity of cortical regions. The authors found that males generally demonstrated higher functional connectivity in the temporal-parietal areas whereas females demonstrated more coherence in frontal areas. Sharma et al. (2018) further examined these differences as a function of task difficulty and utilizing the superior advantage of temporal resolution that EEG offers was able to distinguish sex differences in the sub-processes of MR. Based on the EEG data, Sharma et al. (2018) outlined the sub-cognitive processes of the visuospatial attention allocation network (VSAN), involved in perceptual encoding and stimuli representation, and the mental rotation network (MRN), involved in the spatial transformation of encoded stimuli. Results indicated that males demonstrate advantages over females in the VSAN early in the process of MR with superior bottom-up encoding, evident in parietal-temporal activity whereas females displayed a top-down strategy with parietal activation indicating they may have put more effort into integrating the complex information of the stimuli. In addition, males were found to recruit more right lateralized cortical sites whereas females indicated increased left hemispheric activity, indicating the potential adoption of holistic (right) versus analytical (left) approaches. Interestingly, this pattern has also been found when comparing those in STEM disciplines with humanities or social sciences (e.g. Li and Boyle, 2013). Consequently, it is apparent that different cognitive networks are implicated and this goes some way to explaining the causality of these sex differences in spatial cognition.

EEG allows the researcher to uncover further evidence of strategy use on the cognitive level, as well as potential cortical differences, which help in further understanding the etiology of these well-established group differences. Causality is often lamented as the ultimate aim in a researcher's pursuit of understanding individual differences, but is notoriously complex and difficult to ascertain. Hopefully it is becoming apparent how this neurocognitive tool can expose a layer of understanding in this domain of

education that has traditionally been somewhat unattainable. To further illustrate this potential, let's briefly turn to another useful application of this neurocognitive lens in exploring the issue of the etiological underpinnings of the relationship between spatial ability and STEM success (c.f. [Delahunty et al., 2016](#)).

Uncovering causal explanations in STEM: the case of problem conceptualization

While it is undoubtedly the case that spatial talent plays a key role in success in STEM education, there are no clear explanations as to why this is the case. While the causal relationship between spatial talent and success in STEM is likely multifaceted, a promising area that demonstrates some explanation is in the area of problem solving and particularly the early stages of the problem-solving process. A recent study by [Duffy et al. \(2020\)](#) presents correlational evidence for the role of spatial ability (measured by the Purdue Spatial Visualization Test: Rotations) and problem representation in word problem solving. This is an interesting finding with a sample of engineering students, and taken at a cursory level certainly seems promising in explaining some of this causal relationship we desire. Unfortunately the study suffers from theoretical and empirical limitations. This study would have benefited from a more critical consideration of the area of problem representation which the authors seem to conflate with the external representation only (via student solutions) despite the known phenomenon of internal-external interaction in the problem representation phase ([Delahunty et al., 2020](#); [Schnotz et al., 2010](#)). There is also a failure to control for confounding variables in this study such as reading ability which has actually been shown to be a more significant predictor of word problem solving than spatial cognition ([Kyttälä and Björn, 2014](#)), which is also supported by fMRI data ([Newman et al., 2011](#)). But in fairness to the authors, the internal evidence underpinning problem representation is a very difficult thing to directly observe.

In addressing this issue, and the general issue of problem-solving research in failing to address the early components of the process ([Ohlsson, 2012](#); [Barsalou, 2009](#)), the author's own work has introduced the notion of "problem conceptualization". Problem conceptualization can be operationally defined "as the period of cognitive processing occurring before the externalization of any representation (e.g. a sketch, mathematical expression, verbal communication etc.)" ([Delahunty et al., 2020](#), p. 399). Based on this definition, it is clearly a difficult undertaking to observe cognitive activity that occurs in this process to determine strategy use, that eventually leads to the externalized (or purely internalized) problem representation. In this work ([Delahunty, 2019](#); [Delahunty et al., 2015, 2018, 2020](#)), we have successfully utilized EEG for just this process.

For example, in [Delahunty et al. \(2020\)](#) EEG is applied as part of a mixed-methods study and also synthesized with video protocols of solutions and interviews with participants to explore exactly how word problems are conceptualized in the first seconds of a task. In this work, the EEG data yielded evidence of the activation of significant visuospatial cortical networks (i.e. frontal and parietal regions in theta and alpha frequencies) in the first few seconds of the problem-solving episode, prior to any externalized activity. This suggests that visuospatial cognition is involved within the internal aspects of problem conceptualization of word problems, prior to the representation phase of problem solving. This then, not only supports the importance of spatial cognition to problem representation but suggests that its role is operational in the immediate seconds of perception, prior to representation occurring. This again exemplifies the causal explanatory potential of the method but what is most noteworthy here is in the balancing of methods in our research. While in many cases the interviews that we have conducted about participants' solutions have aligned with the EEG data, there are cases when the EEG data revealed cognitive processes that were not recognized by participants. Synthesizing the quantitative cognitive EEG tool with other phenomenological approaches, such as interviews and stimulated recall episodes, connects the biological-cognitive with the sociocultural-sociohistorical, allowing a more comprehensive insight into causal relationships. For the reader interested in more on this "Cog-Phenom" approach see [Delahunty et al. \(2020, 2018\)](#).

Concluding remarks on EEG for STEM education research

As the previous sections have shown, there is a wide array of application for EEG in the investigation of learning related processes in STEM. EEG has advantages in temporal resolution being able to demonstrate specific reactions to stimuli or the cognitive activity underlying behavioral events. The advent of portable commercial headsets means that this technology may in time find further utility in more ecologically valid manners of research in STEM. There are however some limitations that are noteworthy. For example, the data processing is time consuming and complex and the collection of data is a very sensitive process susceptible to many artifacts. EEG is also quite limited in its spatial resolution and in order to gain more detailed and accurate insights into brain regions associated with learning, the researcher must consult functional imaging methods.

Functional imaging approaches in STEM educational research

This category of imaging methods utilizes the changes in blood flow and metabolic rate to determine areas of activation within the brain. The most commonly used strategy to achieve this is functional magnetic resonance imaging (fMRI) which assesses changes in the oxygenation of blood in the brain ([Banich and Compton, 2011](#)). The use of fMRI has a number of advantages including the ability to measure deep brain structures (see [Fig. 3](#)) such as activity in the hippocampus ([Ward, 2010](#)). Below I review and showcase a number of relevant studies aligning with the core areas of investigating strategies, exploring individual differences and aiming at causal explanations as I have with EEG in the previous section.

Fig. 3 fMRI scan showing activation in structure of the brain (“ENG111: Figure 9.7a” by Rosenfeld Media is licensed under CC BY 2.0).

Investigating cognitive strategies: mathematical problem solving

Picking up from where we left off with the topic of word problem solving in the last section, fMRI studies in the last few years have allowed us some further insight into the complexity of cognition involved. For example, [Newman et al. \(2010\)](#) implemented a study which sought to examine the neurological bases of differences of problem-solving strategy in word problems. They explicitly instructed two groups of university students to use either a spatial (e.g. imagine yourself moving backward and forward on the number line) or algebraic (e.g. representing the verbal information in equation format) approaches and varied task difficulty. They found greater overall activation in key areas such as the parietal and left pre-frontal cortices for the algebraic strategy, which tells us that this approach is more cognitively demanding than the spatial approach. Interestingly, and a key advantage of fMRI being the superior spatial resolution, they were able to compare individuals based on strategy preference and found that those with a preference for algebra had higher activations of the anterior cingulate cortex which is associated with cognitive control ([Mohanty et al., 2007](#)). This finding coupled with the superior working memory capacity of this group (discerned from a reading span test) supports the idea that the algebraic group had a higher working memory capacity and hence more cognitive control in the more demanding algebraic approach. This gives us some further insight into the relationship between strategy preferences and underlying cognitive architecture of individuals.

Whereas EEG data relies on the inference of cognitive functions based on frequency analysis and location, fMRI allows direct observation of spatially accurate cortical activation, including areas within the brain such as the limbic system. This has led to enhanced understanding of different elements of memory function in areas such as arithmetic problem solving. For example, [Grabner et al. \(2009\)](#) found increased activation of the left angular gyrus in adults who self-reported the use of retrieval strategies during arithmetic problem solving. While many studies up to that point had linked this area to the process of arithmetic problem solving (e.g. [Ischebeck et al., 2007](#)), the exact function remained elusive. In the study, [Grabner et al. \(2009\)](#) were able to isolate this region as unique to those who adopted retrieval (compared to procedural) strategies (see [Fig. 4](#)) providing robust evidence for this location in arithmetic fact retrieval and distinguishing retrieval from procedural strategies as involving less cognitive networks. This evidence supports the idea of increasing neural efficacy as a result of learning and again allows STEM educational researchers deeper insights to inform task or pedagogical design.

Lastly, as discussed in previous sections, access to the internal reasoning that occurs during the representation of word problems is notoriously difficult and has led to much debate. In exploring the differences in solving word versus number/equation tasks [Newman et al. \(2011\)](#) found that both strategies involve similar processes on the cognitive neurological level. These included activations of the posterior parietal cortex and interparietal sulcus, which have been associated with problem representation ([Loetscher et al., 2007](#); [Alfred et al., 2018](#)). However, [Newman et al. \(2011\)](#) demonstrated that the word problems elicited significant activation of language centers (Broca’s and Wernicke’s areas) whereas the number problems recruited more visuospatial locations (see [Fig. 5](#)). This nuanced detail provides further evidence of the underlying cognitive processes required for the successful solving of various problem types. This in turn informs the educational researcher and teacher in terms of pedagogical strategies to alleviate barriers to the successful engagement in problem solving by students (e.g. strategies targeted at semantic analysis of word problems vs. visual representations of numeric problems).

Fig. 4 Illustrating differential patterns of activation with retrieval strategies activating left angular gyrus. Data from Grabner, R.H., Ansari, D., Koschutnig, K., Reishofer, G., Ebner, F., Neuper, C., 2009. To retrieve or to calculate? Left angular gyrus mediates the retrieval of arithmetic facts during problem solving. *Neuropsychologia* 47(2), 604–608.

Exploring individual differences and causality: the case of scientific innovative problem solving

Within the realm of science education, a core goal is to develop students inventive and innovative problem-solving capacities (Banks and Barlex, 2014). A core reasoning ability in this context is that of analogy or analogical reasoning (AR) (Krumnack et al., 2013; Brookman-Byrne et al., 2019). While AR has a role to play in many higher-level cognitive processes the actual process itself is complex and research methodologies typically employ regression type designs (e.g. Stamenković et al., 2019) where intelligence tests are used to predict performance or self-report measures such as interviews (e.g. Mozzer et al., 2013) where participants are asked to describe their approaches. Again, these represent a somewhat detracted set of evidence to observe individual differences. While there is considerable debate as to the true validity of intelligence tests with regards their relevance to applied activities (e.g. Richardson and Norgate, 2015) they have been extremely useful in illustrating the types of abilities that underpin success in AR.

In order to fully understand individual differences though, we need to have a look at the manifestation of these intelligence differences in the applied sense and in real time. This is again where a neurocognitive lens can be helpful. It is worth noting at this point that much fruitful work has been done on mapping the neurological bases, including individual differences, of intelligence and for further insight the reader should consult the work of Richard Haier (e.g. Haier, 2011; Haier et al., 2009; Haier et al., 2004). Specific to scientific problem solving this has also been done by Tong et al. (2019) who found increased gray matter volume in the right superior temporal gyrus of young adults more adept at innovative problem solving. This was hypothesized to lead to their superior ability in the semantic integration of heuristic prototypes, key to insightful problem solving (Yang et al., 2016).

In examining individual differences in AR from the neurocognitive perspective Hammer et al. (2019), using fMRI with a large sample, found that individual differences were represented in the executive function and visuospatial networks (prefrontal cortex and lingual gyrus). Of important note was the finding that participants success in AR was contingent on their cognitive skill

(ability to activate) these cortical networks. This not only demonstrates how fMRI differentiated real-time cognitive networks of individual differences but highlights the area of visuospatial cognition once again as an important underpinning mechanism in STEM problem solving. Again, we can see the utility of neurocognitive perspectives in highlighting causal mechanisms of STEM learning. For more on the role of analogical reasoning in supporting science and math problem solving see [Brookman-Byrne et al. \(2019\)](#).

Concluding remarks on fMRI for STEM education research

The use of fMRI for educational research in STEM has many key benefits as can be seen from this brief review. There are however limitations in the capturing of functional data as what is measured is a hemodynamic response which is much slower (normally occurs approximately 2 s after the event) ([Freeman and Quiroga, 2013](#)). This presents issues for studies looking at particular stages of performance in applied tasks, as the data is an average over an entire episode ([Banich and Compton, 2011](#)). Again, this is the trade-off of advantages/disadvantages with EEG. In addition, fMRI requires advanced equipment, normally in the form of medical grade scanners (see [Fig. 6](#)), to undertake and is typically limited to the laboratory. This presents limitations with its application in applied settings such as the science laboratory once again bringing into question issues of validity. However, an emerging neurocognitive method that overcomes this limitation is functional near-infrared spectroscopy which provides spatially accurate measurement of hemodynamic brain responses and can be applied in “unconstrained” contexts. For more on this see [Balardin et al. \(2017\)](#).

Other physiological measures of learning processes

While I have devoted much of this section to the unpacking of some of the potential neurocognitive applications in STEM education research given their complexity, there are other methods available to the researcher in the wider physiological sphere. In the previous sections I have concentrated only on the cognitive processes underpinning typical learning processes in STEM however this is not to say that emotional responses cannot be captured. As we know, emotions, and their impact/association with cognition, have a large role in learning success ([Scrimin et al., 2016](#)) so in this section I will also look at those studies examining emotional aspects of learning with physiological lenses. Here I will try to demonstrate a variety of methods rather than the same depth as I have previously with the neurocognitive tools.

Physiology of emotion: heart rate and electrodermal approaches

Of all emotional variables that can impact the learning process in STEM, mathematics anxiety is possibly the best known and most pervasive area (see [Namkung et al., 2019](#)). While it is clear that math anxiety has a negative effect on the learning process, other research has shown its potential physical impact on health. For example, [Reims et al. \(2004\)](#) found that during a mental arithmetic test, adults’ blood pressure increased and demonstrated poorer recovery in those that had pre-test high blood pressure readings. This has obvious health implications but what about earlier in educational development, particularly in the classroom, and how could it be investigated? [Hunt et al. \(2017\)](#) conducted a study using a sample of primary school children and asking them to wear a portable blood pressure cuff (see [Fig. 7](#)) while solving arithmetic problems. They found that heart rate and blood pressure increased in students with increasing task difficulty (number of digits) but most significantly they found a positive correlation between mathematics anxiety and higher physiological readings (see [Table 1](#)). This highlights potential concerns for the well-being of pupils in

Fig. 6 fMRI scanner (“File:190603 functional magnetic resonance imaging at the Imperial Center for Psychedelic Research. jpg” by Thomas Angus, Imperial College London is licensed under CC BY-SA 4.0).

Fig. 7 Portable blood pressure monitor.

Table 1 Means (and SDs) of heart rate, sysBP and diaBP as a function of problem type.

		Baseline	2-Digit problems	3-Digit problems
Measure	Heart rate	92.00 (15.63)	89.18 (13.17)	89.75 (12.97)
	SysBP	105.51 (16.82)	105.56 (17.29)	109.36 (17.01)
	DiaBP	72.26 (16.98)	74.19 (14.21)	80.87 (17.00)

From Hunt, T.E., Bhardwa, J., Sheffield, D., 2017. "Mental arithmetic performance, physiological reactivity and mathematics anxiety among U.K. primary school children". *Learn. Indiv. Diff.* 57, 129–132.

this context and one which could not be inferred directly for the typically utilized method of self-report measures in mathematics anxiety research. This is potentially useful to the researcher as it is now possible to record these data within the social context of the school and classroom. This offers the potential to record quantitative physiological indices of emotional responses to phenomena of interest, and in a manner conducive to high levels of ecological validity or as part of a multidimensional approach to the measurement of emotional phenomena. As well as furthering our understanding of these emotional components, cognitive processes are also manifested with correlated physiological indicators (e.g. Obradović and Finch, 2017). This again gives the researcher another suite of tools in which to capture data on cognitive processes related to learning in STEM contexts.

Assessing engagement is an important aspect of educational research given the implications that this data would have for teaching and learning designs among other areas. Engagement can be captured in real-time using a physiological approach. Pijera-Díaz et al. (2018) wished to observe arousal states during physics lessons with high-school students and utilized an electrodermal measure. To do this, they employed the Empatica E4 wristband, which measures electrodermal activity from the surface of the participant's skin with accuracy (McCarthy et al., 2016). This device takes the form of a wrist wearable sensor similar to a watch. Pijera-Díaz et al. (2018) found that a predominant occurrence of low arousal was indicated in most lessons and during an exam setting that arousal increased and was correlated with success. These findings not only provide an indicator of task engagement, allowing, for example, a learning sciences researcher to implement a design-based approach to a new task format, but also gives us an insight into a potential threshold of cognitive engagement for academic performance. Although work using in this technology is relatively new in the context of STEM education research, there are some emerging projects appearing in the literature using this technique. For example in engineering education research (e.g. Khan et al., 2019; Villanueva et al., 2018).

As well as investigating cognitive components of task engagement, these wearable sensor devices can also be implemented in the context of quasi-experimental or field experiment research designs. Geršak et al. (2020) demonstrate an example of this where they studied two groups of second grade children who were taught under classical and movement-based pedagogical methods (based on embodied cognition), respectively. The researchers' goal was to explore the impact of physical activity on geometric problem solving and collected multidimensional physiological data from pupils including electrodermal activity, energy expenditure and skin temperature. These were captured using a wearable monitor and paired with an accelerometer to capture activity levels. This allowed Geršak et al. (2020) to determine that the movement group did demonstrate higher physical activity compared to the control, showed higher cognitive activation during the geometry lectures (measured by electrodermal response) and retained knowledge at a better rate 6 months later. Now caution must be exercised here as no effect sizes have been presented by Geršak et al. (2020) so we cannot determine the true effects of the experiment. However, the study does demonstrate the potential value such physiological methods can add to pedagogical research, particularly as it applies to experimentation with specific teaching and learning practices.

Observing physiological differences in expertise: eye-tracking approaches

Eye-tracking or pupillometry has emerged in recent years with various applications in educational research. Eye-tracking works by monitoring the fixations of individuals' gazes and also their pupillary responses (such as dilation as a result of physiological arousal) which can be used to infer cognitive processes such as cognitive load (Bianchi et al., 2020). As an applied example, within the field of teacher education there is always an interest in examining elements of teacher expertise in order to inform practice which traditionally relies on approaches such as observation of novice and expert teachers in practice. Cortina et al. (2015) used eye-tracking, worn by expert and novice teachers during class (see Fig. 8), to assess this topic. They found that in all, expert teachers fixated less on individual students indicating increased monitoring of overall classroom activity compared to those fixations of the novice teachers. However, as the authors integrated the tool with observational data of classroom behavior, they found that the higher fixations were not correlated with behavioral issues of individual students but instead related to the giving of quality feedback to students and engaging in discussion on subject matter. This allowed the researcher a more nuanced look into the manifestation of group differences in teaching approaches, beyond the more obvious hypotheses on classroom management issues.

Eye-tracking works by monitoring the fixations of individuals' gazes and also their pupillary responses (such as dilation as a result of physiological arousal) which can be used to infer cognitive processes such as cognitive load (Bianchi et al., 2020). As an applied example, within the field of teacher education there is always an interest in examining elements of teacher expertise in order to inform practice which traditionally relies on approaches such as observation of novice and expert teachers in practice. Cortina et al. (2015) used eye-tracking, worn by expert and novice teachers during class, to assess this topic. They found that in all, expert teachers fixated less on individual students indicating increased monitoring of overall classroom activity compared to those fixations of the novice teachers. However, as the authors integrated the tool with observational data of classroom behavior, they found that the higher fixations were not correlated with behavioral issues of individual students but instead related to the giving of quality feedback to students and engaging in discussion on subject matter. This allowed the researcher a more nuanced look into the manifestation of group differences in teaching approaches, beyond the more obvious hypotheses on classroom management issues.

One very useful benefit of eye tracking methods today, is their potential application to a wide variety of research participants. For example, application of some of the previously explored tools to young children in pre-school settings may prove problematic. For instance, even with mobile EEG, there is still quite a significant headset to be worn and the method itself is quite sensitive to extraneous factors such as excessive movement or physical interference. This in all likelihood rules this technique of capturing cognitive data an unsuitable approach. Eye-tracking however can be applied due to its additional robustness and variety of means data gathering. Today, eye tracking devices come in a variety of forms ranging from the glasses in Fig. 8 to remote eye tracking devices, such as the one shown in Fig. 9. Here the eye tracking device is integrated with the screen to be used for displaying research stimuli and the position of the child's seat is also depicted (c.f. Hessels and Hooge, 2019).

These types of technology clearly open up a myriad of possibilities for the STEM education researcher interested in cognitive process that underpin learning phenomena of interest. Given the interest that STEM education researchers have in spatial cognition, it would be useful to have a technique such as eye-tracking available in order to gather data on the early stages of skill development, say in preschoolers. Verdine et al. (2017) conducted such a study with 79 three-year olds and aimed to observe the interaction of socioeconomic status (SES) with differences in the cognitive processing of geometric shape names. The study employed an eye-tracking approach using an observational setup similar to that in Fig. 9. The results indicated that students in the lower SES took significantly longer to fixate on target geometric shapes and spent less time looking at them, revealing a distinct processing difference. Of most interest, performance on this task was predictive of spatial ability at age 5, suggesting that the ability to process geometric shape names may be foundational for later spatial development. This suggests that, like many wider areas of

Fig. 8 Eye-tracking wearable headset ("Eye tracking study" by Nestlé is licensed under CC BY-NC-ND 2.0).

Fig. 9 Remote eye-tracking setup where the eye-tracker is mounted to the screen frame. From Hessels, R.S., Hooge, I.T.C., 2019. Eye tracking in developmental cognitive neuroscience – the good, the bad and the ugly. *Dev. Cogn. Neurosci.* 40, 100710. <https://doi.org/10.1016/j.dcn.2019.100710>, p. 40.

STEM education (e.g. Betancur et al., 2018), that SES is another variable that impacts the development of spatial cognitive abilities and from a young age. It also gives some insight into the potential etiological precursors to the successful development of spatial talents. These example studies demonstrate the broad applicability and rich data that the eye-tracking approach can generate.

Concluding remarks on physiological approaches in STEM educational research

As this brief overview shows, there are many advantages to the implementation of physiological methods to STEM learning investigations. They are in general less invasive than their neurocognitive counterparts and thus allow more widespread application. They are also applicable to a wider variety of potential participants, particularly young children. They do however suffer from the limitation that the researcher is not observing direct evidence of cognition per se, but must make inference of the underlying cognitive activity exemplified in physiological data. However, physiological data collection methods can be integrated with neurocognitive methods through software platforms such as iMotions (<https://imotions.com>) thereby overcoming some of these limitations. These approaches offer the STEM education researcher the potential to capture quantitative evidence of the manifestation of emotional responses, as well as data on cognition processes, of applied activities such as those undertaken in the school, classroom, lecture hall or even the home.

Broader considerations for application

This article has presented a broad overview of some of the neurocognitive and physiological approaches that have been applied to the field of STEM education research in recent years. While it gives a broad sample of the work carried out under a variety of themes and encompassing several phenomena of interest to the STEM education researcher, it is not intended to be an all-encompassing critical review and the reader should dig further into the studies and topics outlined for application in their own work. These neurocognitive and physiological methods have been applied to a relatively small number of topics in the field, but as the technology develops the application of these approaches may become even more widespread. Nonetheless there are some considerations worthy of noting.

There is much debate and controversy about the applicability of neuroscience concepts to education. One such area of contention is in the potential for these methods to assume the dominant explanatory position in education, at the expense of sociocultural perspectives (cf. Hall et al., 2014). It is important to reiterate at this point, that this is not the case and at all times in this article I have attempted to demonstrate how a particular neuroscientific or physiological approach can augment our understandings from wider theoretical perspectives. The key in all of this is in achieving an appropriate balance of methods and drawing conclusions and implications with cognisance that neuroscientific or physiological explanations can never explain the totality of learning. This issue in part relates to how one analogizes learning, as briefly mentioned earlier in the article where I explored the notion of a complex adaptive systems (for more depth on this discussion of analogies please see Delahunty and Kimbell (2021)), but also relating to how we conceptualize educational research as a discipline.

Without delving into a nuanced discussion of this issue here it is useful to highlight that, in the Anglo-American tradition, educational research has been conceived of as based on investigative lenses from the foundational disciplines of sociology, philosophy, psychology and history. Lawn and Furlong (2009) would argue that these disciplinary contributions have waned in recent times, but Biesta (2020) reminds us that in this Anglo-American tradition it is arguable as to whether educational research can be classified as a basic discipline in its own right and therefore must be multi/inter-disciplinary (pp. 86–87). The danger that emerges then in the context of STEM education research, and aligning with the critique levied by Hall et al. (2014), is the potential for premature application of insight from neurocognitive or physiological research to explain or inform learning practices. This is a salient concern for any context of education and educational research given the desire of policy makers to utilize, supposedly objective (Gillborn et al., 2018), quantitative data to derive educational policies. This worry is heightened when the quantitative data in question, is derived from, say, a neuroscientific perspective given the seductive allure of these data in supporting particular ideas (Weisberg et al., 2008). However, returning to the idea of foundational disciplines of educational research, it is doubtful that educationalists, who oppose the idea of neuroscience and physiological methods, would levy the same complaints to the field of psychology and its impact on educational practices.

Of the disciplines, psychology has had one of the strongest contributions and impacts on educational research but even this field of research is somewhat limited itself, when applied to questions of educational research. To take an example from Thomas et al. (2019), consider the widely circulated analogy of the computer metaphor to describe fundamental components of learning such as working memory. As this process assumes a general, context independent architecture, one would hypothesize that gains in one domain would translate to wider areas. However, it is well supported that such cases of “far-transfer” are extremely rare (Bransford and Schwartz, 1999). The implications here are that the brain must therefore utilize mechanisms of cognition that are less general than currently considered in cognitive theory and so there are “aspects of learning that simply do not make sense except with respect to the brain” (Thomas et al., 2019, p. 478). Taking this idea further, the situated or contextually specific nature of learning processes actually strengthens the role of sociocultural perspectives in explaining educational realities, but in order to gain a complete picture, the place of neurocognitive and physiological methods is underscored.

Conclusion

In order to achieve more complete understandings of STEM learning processes, educational researchers are required to adopt an open disposition to interdisciplinary collaborations. This must be conducted while maintaining a critical stance acknowledging the specific aspects of the learning process that the methods, reviewed in this article, are able to capture data on, and to not put so much weight on these data at the expense of missing vital perspectives offered by other disciplinary lenses. Neuroscientific data is particularly sensitive given the seductive appeal that these types of data have in the political landscape of academic publishing and funding applications. Therefore, I wish to conclude with a consideration for the STEM education researcher, inspired by Biesta’s (2020) discussion on the culture of measurement in education. That is, when considering the application of these methods to a research study ask yourself, are you measuring what you value or valuing what you measure? Put more plainly, start with the phenomenon of interest and after careful theorizing and initial research, then ask yourself if one of these methods will be illuminating in your particular research study.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia–Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

EDITORIAL BOARD

Jason Beech

School of Education Culture and Society, Faculty of Education, Monash University, Melbourne, Australia

Qing Gu

UCL Centre for Educational Leadership, UCL Institute of Education, University College London (UCL), London, United Kingdom

Graham Hingangaroa Smith

Distinguished Professorial Chair, Te Toi Ihorei ki Purehuroa Massey University, Palmerston North. New Zealand

Therese Hopfenbeck

University of Melbourne, Melbourne, Australia

Nataliya Ivankova

The University of Alabama at Birmingham, Alabama, USA

Huia Jahnke

Professor of Māori and Indigenous Education in Te Pūtahi a Toi School of Māori Studies at Massey University, Palmerston North New Zealand

Berit Karseth

Professor at the University of Oslo, Department of Education. Oslo, Norway

Kenneth Leithwood

University at Buffalo, State University of New York, USA

Xiufeng Liu

Emeritus Professor, university of Toronto, Toronto, Canada

Margaret Maaka

Professor, College of Education, University of Hawai'i at Mānoa, Hawai'i, USA

Diane Mayer

Professor Emeritus, University of Oxford, UK

Dan McCaffrey

Educational Testing Service, Princeton, NJ, United States

Judy Parr

University of Auckland, Auckland, New Zealand

Jeong-eun Rhee

Long Island University, New York, USA

Fazal Rizvi

The University of Melbourne, Melbourne, Australia

Theresa Rogers

Professor, Faculty of Education, University of British Columbia, Canada

Chika Sehoole

University of Pretoria, Pretoria, South Africa

Roland Sintos Coloma

Wayne State University, Michigan, USA

Roger Slee

Diamond Jubilee Chair of Disability & Inclusion, School of Sociology & Social Policy, University of Leeds, UK

Ninni Wahlström

Linnaeus University, Växjö, Sweden

Lei Wang

Beijing Normal University, Beijing, China

Everard Weber

Research Associate, South African Chair in Teaching and Learning—UJ Academic Advisor, Future Professors Programme—UJ University of Johannesburg (UJ), Johannesburg, South Africa

Ian Wilkinson

The Ohio State University, University of Auckland, New Zealand

David Yaden

Dept. of Teaching, Learning and Sociocultural Studies, College of Education, University of Arizona, USA

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati MamoeNgati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "universities" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019). Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

tion, [UK.gov](https://www.uk.gov/), and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019). Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 12: Qualitative, Multimethod, and Mixed Methods Research

Nataliya V Ivankova

© 2023 Elsevier Ltd. All rights reserved.

Introduction

Research in education has a long history of applying different methods and forms of inquiry to address complex education issues. While a quantitative research approach with its focus on standardized measurements and objective scores has prevailed in education research, other forms of inquiry, such as qualitative and mixed methods research, have gained popularity in education studies. Qualitative research that aims at exploring individuals' experiences with and perceptions of social phenomena has achieved recognition as a means of exploring and understanding the complexity of the teaching and learning process. Its rightful position in international education research was captured through a representative number of articles addressing philosophical and methodological aspects of qualitative research in the previous, third edition of the *International Encyclopedia of Education*. Many of the chapters in the current volume provide updated information on those topics, but also reflect the new developments in conceptualization and conduct of qualitative research in education.

Recently, mixed methods research has been added to the toolkit of education researchers. Mixed methods research quickly became the methodology of choice due to its ability to meaningfully integrate qualitative stakeholder engagement methods with quantitative outcome-focused approaches to promote an integrative thinking for addressing complex education issues. The growing popularity of mixed methods in education research is reflected in the number of chapters in this volume that are devoted to conceptual and procedural issues of designing, conducting, and reporting mixed methods studies in education. In contrast, mixed methods research was represented by one article written by A. Tashakkori and I. Newman in the previous, third edition of the *International Encyclopedia of Education*.

While there is no clear distinction between mixed methods and multimethod research, and mixed methods scholars' perspectives vary in this regard, we acknowledge the existence of fundamental similarities between these two approaches. They both aim at a deeper, comprehensive, and fuller understanding of the problem and include multiple forms of evidence (Hunter and Brewer, 2015; Flick, 2017), which are integrated to produce knowledge that is more than the sum of the individual quantitative and qualitative components (Fetters and Freshwater, 2015) (see J. Schoonenboom's chapter on mixed methods and multimethod research in education in this volume for a more detailed discussion). Moreover, as claimed by A. Skukauskaite in this volume, some traditional forms of qualitative inquiry are multimethod in nature because they rely on combination of alternative methods to produce more in-depth conclusions about the studied problem. So, we encourage the readers to think about these forms of inquiry from a pragmatic perspective with the focus on the value added that the combination of multiple methods offers to understanding education issues.

This volume consists of 75 chapters that address different aspects of qualitative, multimethod, and mixed methods research from philosophical and conceptual issues, to design and application of methods, and to presentation and reporting of data and findings. Consistent with the international focus of the Encyclopedia, the volume includes chapters written by the authors from 21 countries representing 5 continents. Of 128 authors who contributed chapters to this volume, about 48% are international. This speaks to the popularity of qualitative, multimethod, and mixed methods research in education across different countries and continents. Such broad international representation across the chapters also helps capture variability of methodological perspectives related to conceptualizing and using these research approaches shaped by unique historical developments, epistemological preferences, and contextual influences observed in these and similar countries. What is common across the authors is the recognition of the many advantages that such methods provide to address a wide range of education issues that require in-depth exploration of the users' experiences and viewpoints as well as a comprehensive treatment of the problem from multiple angles and multiple perspectives.

The chapters are organized into eight sections, three of which are devoted to qualitative research and five sections focus on multimethod and mixed methods research. The following is a detailed account of each section to help orient the readers to their structure and content.

The first section includes eight chapters that address philosophical and theoretical underpinnings of qualitative research. The first chapter under the same title by E. Boswell and W. Babchuk sets the tone for the whole volume by addressing the role of philosophy and theory in research in general and qualitative research, in particular, with implications for multimethod and mixed methods research. The next chapter by M. Hammersley provides a comprehensive historical overview of the use of qualitative research methods in education and sets the stage for the discussion of different qualitative research approaches and their applications in education research in the chapter by P. Delmas and R. Giles. A. Ryen engages the readers in a discussion of ethics and politics in qualitative research and their influence on how qualitative results are viewed and interpreted by different audiences. The other four chapters focus on applications of different theoretical perspectives to guide qualitative studies in education, such as the role of critical theory in qualitative research in education (J. Ryoo and J. Crawford), and examples of applications of feminist and gender theory (C. McLewis, J. Gutzwa, and S. Hurtado), critical race theory (T. Loder-Jackson, M. Bodine Al-Sharif, C. Jones, M. Files, and C. Wiggins), and queer theory (B. Wozolek). The importance of these theoretical perspectives for informing qualitative inquiry has been well recognized (Creswell and Poth, 2018; Kincheloe and McLaren, 2011; Winkle-Wagner et al., 2019).

The next section consisting of 12 chapters focus on different qualitative research designs and approaches, the design and procedural features, and illustration of their use in research in education. The first six chapters address the established qualitative research designs and approaches, often referred to as “traditions of qualitative inquiry” (Creswell and Poth, 2018; Hays and Singh, 2011), and include case study (R. Stake and M. Visse), grounded theory (W. Babchuk and E. Boswell), phenomenology (N. Friesen), narrative (S. Chung and J. Clandinin), ethnography (A. Skukauskaite), and autoethnography (S. Pensoneau-Conway). Each chapter offers a theoretical foundation and a practical application of the discussed approach capitalizing on the new developments in conceptualizing and applying these designs while illustrating innovative thinking. Other chapters in this section provide a more extended perspective on applications of qualitative research approaches in pursuit of specific purposes, such as responding to cultural diversity through action and community-based participatory research (R. Bead, A. Ortiz Aragon, and E. Stringer), addressing community needs by engaging in an oral tradition of storytelling (C. Nakhid and A. Fernandez Santana), and using discourse analysis as a space of signification through communication and meaning making (L. Suci). An innovative chapter by J. Greenwood explores interconnections between art and qualitative research, while a chapter by M. Danesi provides insights into semiotics as a form of qualitative inquiry. The chapter by M. Patton underscores the utility of qualitative research for evaluating educational interventions by connecting evaluation questions to intended users and selecting appropriate methods.

The third section focuses on qualitative research methods and their application in education research from a new or updated angle. Each of the 13 chapters discusses a specific qualitative method or strategy, such as approaches to sampling and collecting qualitative data (M. Koro, N. Fairchild, A. Benozzo, and T. Löytönen), using qualitative interviews (S. Brinkmann), conceptualizing focus groups (A. Welker and G. Kamberelis), doing naturalistic observations (J. Schostak), including document analysis (T. Rapley, K. Ardron, D. Littlefair, K. Mulholland, and N. Jenkins), engaging with photo voice (H. Meyer, L. Dell, and R. Gibson), and conducting participatory photography (G. Holm). Several chapters address different approaches to qualitative data analysis including inductive thematic analysis (P. Mihos) and content analysis (P. Mayring). The chapters discussing rapid qualitative research (C. Vindrola-Padros, G. Chisnall, and S. Kumpunen) and conducting qualitative research in online spaces (H. Gerber) emphasize the advances in the application of the established qualitative methods in new research environments. The last two chapters in this section address important issues of establishing quality in qualitative research (L. Cain, R. Williams, and V. Bradshaw) and the advantages and caveats of triangulating multiple methods and data in qualitative studies (A. Pratesi), thus providing a transition to multimethod and mixed methods research which is the focus of the next four sections in this volume.

Section four opens with the chapter by J. Schoonenboom, in which she discusses the foundational aspects of multimethod and mixed methods research and outlines the design decisions important for collecting, combining, and developing multimethod and mixed methods datasets. The next chapter by A. Tashakkori and late I. Newman is an updated chapter from the third edition of the Encyclopedia. In this chapter, the authors provide a foundational overview of mixed methods research using the new developments in the mixed methods field and discuss the advantages of integrating multiple methods in research in education. Five chapters that follow explore philosophical and conceptual premises of mixed methods research offering current perspectives on philosophical underpinnings of the mixed methods approach (P. Shannon-Baker), conceptual frameworks to guide applications of mixed methods research (V. Plano Clark, N. Ivankova, and N. Yang), transformative mixed methods research (D. Mertens), and the role of culture in conducting mixed methods studies in education written by a team of researchers from Jamaica and led by L. Cook. The chapter by E. Creamer delves into the concept of integration in mixed methods research and the philosophical assumptions that facilitate meaningful integration of multiple data, methods, and approaches in mixed methods and multimethod studies.

Section five is devoted to the methodological aspects of designing integrated multimethod and mixed methods studies. This topic has received a lot of attention in the mixed methods literature with discussions ranging from advancing mixed methods design typologies (Creswell and Plano Clark, 2018; Greene, 2007; Morse and Niehaus, 2009; Tashakkori et al., 2021) to typology-free alternative viewpoints (Guest, 2013; Maxwell, 2013; Nastasi et al., 2010). Ten chapters in this volume provide current thinking on different topics within the spectrum of the mixed methods research process and the “how-to” of a mixed methods study. C. Tajima and M. Fetter’s chapter offers an overview of mixed methods research designs using a typology-based approach, whereas J. Maxwell’s chapter on designing integrative mixed methods research presents an interactive concept of design that emphasizes the unique role of the study components and their interaction in the planning and conduct of a mixed methods project. B. Smit, V. Scherman, and L. Liebenberg discuss the role of the qualitative research approach in designing mixed methods studies, and P. Pluye and Q. Hong define and illustrate the concepts of convergence and divergence in mixed methods research. Other chapters in this section cover the logistics of designing and implementing mixed methods studies, including mixed methods sampling and data collection (N. Leech and C. Donovan) and integration strategies (J. Schoonenboom), approaches to mixed methods data analysis (S. Vogl) and mixed methods analysis software (U. Kuckartz and S. Rädiker), quality assurance in mixed methods research (K. Collins), and ethical dilemmas arising from integration of multiple methods (C. Poth, E. Creamer, and L. Cain).

The sixth section combines 10 chapters that illustrate the intersection of mixed methods research with other approaches and designs to address complex education research problems. A concept of methodological intersection has recently emerged in the mixed methods literature to describe research situations when two or more research approaches are intentionally joined within a study design (Plano Clark and Ivankova, 2016). Three chapters discuss the logistics, advantages, and challenges of intersecting mixed methods research with traditional qualitative research designs, such as case study (V. Plano Clark, L. Foote, and J. Walton), grounded theory (E. Creamer), and phenomenology (I. Mayoh and J. Colditz). A chapter by H. White and Y. Ting illustrates the advantages of intersection of mixed methods with quantitative randomized controlled trials in education. At the methodological level, D. Mertens addresses the long-established practices of intersecting mixed methods with evaluation, and N. Ivankova and N. Wingo provide a framework for intersecting mixed methods with action and community-based participatory research approaches.

More recent developments in the intersection of mixed methods with other methodologies include combining mixed methods research with network analysis (D. Froehlich), Delphi method (M. Taghipoorreynah), qualitative comparative analysis (H. Kane and L. Kahwati), and translational research (N. Ivankova, J. Anderson, I. Herbey, L. Roussel, and D. Kim). These chapters illustrate how applying mixed methods research can enhance established designs and methodologies to better address education problems.

Section seven includes nine chapters showcasing different applications of multimethod and mixed methods research in education studies. A chapter by C. Poth and E. Bullock specifically focuses on mixed methods research design practices to address complexity in education. K. Niglas and coauthors describe the logistics of conducting large-scale mixed methods studies in education, while D. Watkins and N. Johnson discuss advancing education research by using mixed methods with existing data. Methodological flexibility of mixed methods research provides a platform for its application in developing culturally tailored interventions (B. Nastasi) and for enhancing systematic literature reviews (P. Onghena). Other chapters provide insights into innovative applications of mixed methods research in combination with other methods, such as geographic information systems (N. Bagheri), art and artistic practices (P. Shannon-Baker and L. Smith), survey methods (J. Hitchcock and A. Crean Davis), and web-based technologies (J. Salmons).

The last section consisting of six chapters provides applied information on how to propose, report, and visualize qualitative, multimethod, and mixed methods research in education. Chapters on developing a qualitative research proposal by M. Weaver-Hightower and on writing a qualitative research report by J. Drisko offer practical advice to those who plan to propose a qualitative study or need to publish findings based on qualitative data. The latter chapter also describes the process of submitting a qualitative manuscript to a journal, explains a peer review process, and suggests strategies for optimizing article acceptance rates. Two chapters provide advice on writing a successful mixed methods research proposal (J. DeCuir-Gunby and W. McCoy) and on preparing journal manuscripts based on mixed methods studies (J. Gothberg and A. Sterenberg Mahon) that are, reportedly, more difficult to publish due to their length and scope (Bazeley, 2015; Creswell, 2022). This section concludes with two chapters that address different types of qualitative and mixed methods visualizations that enhance reporting by using joint displays (T. Guetterman) and improve understanding of information by developing visuals to illustrate the methodological features of a mixed methods study (M. McCrudden).

We hope that the collection of the chapters in this volume responds to the many interests and needs in qualitative, multimethod, and mixed methods research of the Encyclopedia readers. A balanced approach to presenting theoretical and methodological information and practical “how-to” applications in this volume chapters aims at ensuring the readers’ diverse needs are met and serves as a safeguard for their understanding and applying the information. To optimize the learning experience and to expand the readers’ knowledge on the topics of interest, we cross-listed the chapters where possible across the volume, thereby providing the readers with points of reference to other chapters that discuss the same or similar topics in more depth. In conclusion, we wish the readers an enjoyable journey into qualitative, multimethod, and mixed methods research that the chapters in this Encyclopedia volume offer.

Glossary

Abduction inferring an apt conclusion based on the iterative evaluation of data against possible, plausible explanations

Audit trail a set of documents and resources showing the timing and rationale for key decisions in the research process

Axiology the nature of, and study of, values or of the origin of the values conferred on something

Bracketing the practice of documenting—and setting aside—personal views and experiences related to the subject of inquiry, particularly popular in some forms of phenomenological research

Deduction reasoning from the general to the specific, often in the form of strict hypothesis testing that aims to predict something about a population based on a sample

Emic denotes the ‘insider’ perspective of participants at the core of the study

Epistemology the study of knowledge and ways of knowing, and of the nature of evidence or proof

Ethnography the study of a culture-sharing group or some aspect thereof; a term representing both a process and a product of research (*an ethnography*)

Etic denotes the ‘outsider’ perspective of the researcher

Induction reasoning from the specific to the general, often in the form of exploratory research questions that seek to build more knowledge about an understudied phenomenon or community

Member checking any of multiple respondent validation procedures that the researcher uses to verify their findings and interpretations

Memo reflexive documentation of a researcher's insights, methods, decisions, and possible biases throughout a project

Methods specific procedures chosen in alignment with the guiding philosophical assumptions and central questions of the researcher

Methodology a comprehensive approach to research that encompasses the abstract and concrete components of research design and implementation including ontology, epistemology, axiology, and methods

Ontology the study of perceptions of reality and the nature of being

Paradigm an overarching worldview that guides research processes and encompasses a researcher's ontology, epistemology, axiology, and methodology

Positionality a researcher's practice of considering the implications of power dynamics in the research process and how these dynamics produce advantages, disadvantages, biases, or limitations

Positivism the paradigmatic view that a singular, objective reality exists and that it can be accurately observed and measured via scientific inquiry

Post-positivist describes the assertion that a singular objective reality exists but can only be approximated through scientific inquiry

Qualitative research an umbrella term used to designate related approaches that emphasize inductive reasoning, collecting data in natural settings, and understanding participants' points of view

Reflexivity the process whereby a researcher reflects on their own social location, possible biases, and unique insights

Symbolic Interactionism the paradigmatic view that assumes one's social experience are mediated through social interaction mediated by personal and social interpretations of language and other symbols

Teleology the study of time, completion, temporality; perspectives on the contemplation of the end-points of an event or state of being

Theory a way of explaining observed reality and proposing relationships among concepts, people, groups, or sets of conditions

Chapter introduction

Qualitative inquiry is a naturalistic approach to empirical research, one that privileges a participant's perspective over that of the researcher. Qualitative practitioners affirm that the expertise that inheres in individuals and communities holds a wealth of potential for social research. By plumbing the depths of people's lived realities, qualitative research constitutes an equal and worthy counterpart to quantitative sciences and other research methodologies. **Qualitative research** is "an umbrella term used to designate a family of approaches that emphasize inductive reasoning, collecting data in natural settings, and understanding participants' points of view" (Babchuk, 2019, p. 1). Although there are arguably minor distinctions between the terms *qualitative inquiry* and *qualitative research*, these terms are used synonymously throughout this chapter.

Sometimes the task of understanding an abstract set of concepts is made easier by contrasting these concepts with related, but divergent ideas. Although most qualitative scholars view qualitative inquiry as equally valuable to quantitative research, it can be useful to describe the two in terms of how they differ, in order to more fully emphasize the unique features of a qualitative orientation that set it apart and add to its value. Therefore, passages that set qualitative approaches against a backdrop of quantitative science do so only in the hope that readers more familiar with quantitative designs can draw on this knowledge to learn the dialectical ways to understand what qualitative research offers. Given that the history of qualitative research developed partly as a response to the dominance of quantitative approaches, the two are juxtaposed at times throughout this chapter in order to give readers opportunities to compare and contrast them before the introduction of mixed methods at the conclusion of the chapter.

What distinguishes a qualitative approach from others is an emphasis on the perspective and agency of participants in a particular population or culture-sharing group, and sometimes a commitment to participants' direct participation in planning, designing, and implementing research. Additionally, qualitative science is distinct from quantitative science in that it does not rely on hypotheses to guide the research process, nor does it typically attempt to establish causal connections among variables. Erickson (2018) has written that, "The qualitative researcher first asks, 'What are the kinds of things (material and symbolic) to which people in this setting orient as they conduct everyday life?'" (p. 36). This style of inquiry prioritizes language and discourse, both in data collection methods such as extensive interviews as well as in creating research reports and other deliverables that are produced as outcomes of a study.

Participant observation methods (see *Naturalistic Observation*, this volume) and unstructured or semi-structured interviews are popular methods of qualitative data collection that produce the rich, detailed verbiage and "thick description" that are trademarks of qualitative research (Geertz, 1973). Prolonged engagement in the field and immersive, comprehensive data analysis are part and

parcel of a qualitative approach, as are researchers' candid reflections on their role in shaping research findings and interpretations thereof. In the qualitative realm, researchers acknowledge that people are experts on their own lives (Delpit, 1988, p. 297). The participant functions as the expert in the study. This contrasts with quantitative paradigms wherein the researcher commonly adopts a top-down, paternalistic stance. This stance has been imagined as the distant or impersonal researcher donning the mantle of power to administer a 'treatment' to a 'subject' or treating people as anonymous, extracted data sets.

A qualitative researcher strives to adopt a deeply humanist ethos and a profound respect for the participants as complex and holistic beings worthy of dignity throughout the research process. This is sometimes referred to as practicing a duty of care, or an "ethic of care" (Matteson and Lincoln, 2009). Honor, respect, and a collaborative spirit join the qualitative researcher with participants in a dialogic exchange that does not shy away from the fact that the research experience itself is intersubjective. An interview, for example, is a co-construction of knowledge between individuals socialized through intersecting lenses of class, race, gender, culture, and many other aspects of biography that fashion both interviewer and respondent perspectives.

Chapter overview

Part I of this chapter explains some philosophy concepts that are foundational to the assumptions guiding qualitative designs. In Part II, these assumptions are shown to have guided the historical development of overarching grand theories and paradigmatic taxonomies. The application of theory and philosophy to contemporary qualitative methodology is taken up in Part III, including how such values and practices are incorporated into mixed methods research. The chapter concludes with some ideas about future directions within qualitative inquiry.

Part I. Philosophical assumptions of qualitative research

Introduction to Part I

Imbricated with some of the broad theories in qualitative inquiry are the guiding philosophical assumptions that underly most qualitative projects, even if they remain unacknowledged or minimally articulated. These include a preference for inductive over deductive reasoning, a commitment to reflecting on the researcher's unique skills and possible limitations, candor and transparency about the research process, and humanist ethics that course throughout all qualitative inquiry. The term *qualitative research* entered the social sciences in the 1960s (Bogdan and Biklen, 2007, p. 2). Early qualitative innovators emphasized "human flexibility, the importance of the genesis of the self, the definition of the situation, and the role of the community in the social process" (Deegan, 2007, p. 14). Rather than isolating variables in a laboratory for precise quantitative measurement, qualitative approaches embrace the complexity of the human condition and endeavor to understand the fundamental processes and conditions that knit people together into communities and culture-sharing groups. These features position qualitative researchers to offer detailed and context-specific information about known and novel situations across diverse communities and in variegated circumstances of life and work. A qualitative orientation is moreover a natural outgrowth of many academic disciplines, provided that the specific philosophical assumptions of a discipline are interrogated before designing research.

Distinguishing ontology from epistemology

Questions about the nature of knowledge behoove us to make ourselves aware of the limits of our knowledge (Schneeg, 2014, p. 46). **Epistemology** is the study of ways of knowing, and of what counts as evidence in various research paradigms. Epistemologies are not the only philosophical basis for qualitative research approaches, however. Axiology, teleology, and especially **ontology**—the nature of being and the study of that which is 'real'—all matter as philosophical pillars supporting the epistemological foundations of a research study. Epistemology presupposes ontology, but many students of qualitative research learn these in reverse order. First, one must conceive of an entity and its indicators in whatever reality one adopts. Only then can one consider the epistemological axes of that reality—how we come to know of, and prove, its existence. These axes include the nature of facts, knowledge, evidence, and observation: what counts as knowing and how we go about gathering and verifying knowledge.

Humans are socialized to accept some forms of knowledge uncritically, and thus epistemology is often obscured by strong social norms reinforcing what is taken for granted by one's surrounding community. For example, the concept of a 'day' has ontological roots in the regular cycle of the sun; however, dividing this concept into 'hours' reveals how society has organized and expressed our experience of the solar cycle—one which we could easily conceptualize in other ways. Whereas solar and lunar cycles are ontological, the concept of a seven-day week is purely epistemological; there is nothing inherent in nature that distinguishes a weekday from a weekend. Only habit, indoctrination, and social organization accomplish this cultural feat.

A 'weekday' is an episteme: a tool of thought that humans use to think about and talk about reality. Some tools of thought are innocuous but no less revealing of the biases limiting those who coin them. An innocent example that illustrates the creation and application of an episteme is the term 'ornamental shrub'—it defines whole categories of plant species based on human uses (or lack thereof) for those species, rather than in line with botanical characteristics. By circulating these terms, the creators of such nomenclature trade ontology for epistemology: they conflate the nature of the thing itself with how they label that thing within their chosen, culturally conditioned, and narrow-sighted knowledge systems.

The difference between ontology and epistemology might at first strike readers as a heady philosophical conundrum or perhaps a trifle, but qualitative researchers would be well-advised to devote some energy to clarifying which concepts and definitions are embedded in a project's design premise and whether the participants, funders, reviewers, and other stakeholders share those ideas. It is also crucial to anticipate the offense taken, or even backlash, when controversial assumptions belie an ethnocentric or otherwise limited bias that undermines the inclusion and emancipation at the heart of qualitative research.

Logics employed in qualitative research

Accompanying the static assumptions that qualitative researchers bring into their work with them are philosophical processes, or logics, that structure their reasoning and decision-making throughout a project. A **logic** is merely a system of inputs and outputs, and more than one type of logic might be needed to move the project—especially the data analysis—from beginning to end. Two basic logical processes are **induction** and **deduction**, with the latter being the default approach to quantitative science. The former, inductive reasoning, is a signature element of qualitative research, and there is room for other forms of reasoning to support induction, and even to validate it. These include abduction, retroduction, and transduction (see [Lipscomb, 2012](#); [Belfrage and Hauf, 2017](#); and [Visokolskis, 2021](#), respectively).

Although the terms are applied slightly differently in syllogistic and rhetorical applications than in this chapter, the basic meanings of induction and deduction hold in qualitative research: induction moves from the specific to the general while deduction moves from the general to the specific. Whereas deductive reasoning is well suited to a quantitative project that aims to predict the behavior of a population based on the results of a sample, inductive reasoning provides a path for gathering specific data, analyzing it, and then making generalizations that may or may not be predictive of people outside the study sample. Induction may be used to generate hypotheses, and deduction is apt for testing those hypotheses. Induction restrains itself from presupposing too much about the sample or the data and is better applied to research questions and problems requiring intellectual exploration. Deduction, conversely, would presuppose a great deal in order to invent a treatment, experiment, or intervention that hopes to confirm (or deny) a pre-established prediction through specific hypotheses identified prior to data collection.
